Ciprofloxacin Fluoroquinolone/quinolone antibiotics ✗✗/◈◈/≈≈≈/☼	Binding may occur with simultaneous intake and inhibit absorption and bioavailability of both agents. Decreased therapeutic activity probable with interaction; minimal effect with separation of intake. Limited evidence on long-term effects.	Avoid zinc, or separate intake during short-term therapy. Separate intake by several hours.
Clobetasol Corticosteroids, topical ⊕⊕	Coadministration of zinc and clobetasol (and biotin) may enhance therapeutic effect in treatment of inflammatory dermatological conditions.	Consider coadministration, with biotin, for synergistic effect. Complement with low-dose copper with long-term use.
Corticosteroids, oral ≈≈/✗	Adenohypophyseal-adrenocortical network helps maintain circulating zinc and mobilize zinc from tissue stores. Internal or exogenous glucocorticoids can affect zinc metabolism. In particular, oral corticosteroids can elevate urinary zinc excretion and lower serum zinc levels. Coadministration of zinc may prevent or reverse depletion, but research is needed to rule out potential interference or adverse effects.	Coadminister to prevent depletion. Complement with low-dose copper with long-term use. Watch for clinical signs of zinc depletion with extended steroid therapy; lab tests often unreliable.
Estrogens, conjugated Oral contraceptives (OCs) Medroxyprogesterone Estrogen replacement therapy (ERT) ≈≈≈/⊕⊕	OCs may decrease serum levels of zinc. However, conjugated estrogens and medroxyprogesterone may reduce previously elevated urinary zinc excretion in osteoporotic postmenopausal women. Further research is warranted to determine varying effects of different estrogen compounds in their respective patient populations.	Women using OCs may have increased needs for zinc based on potential depletion, as well as possibly higher needs for folate and vitamins B_{12} and B_6. ERT may enhance zinc status. Individual evaluation of safe and effective hormone dosage levels necessary.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Histamine (H_2) receptor antagonists Antacids Gastric acid—suppressive medications ≈≈≈	Agents that interfere with normal acid environment of the stomach can impair zinc absorption and reduce availability; although among H_2 blockers, cimetidine appears to be an exception. Adverse effects on zinc status may be slow to develop and difficult to assess. Administration of zinc can prevent or reverse depletion and enhance healing of gastric tissue damaged by ulceration.	Coadministration of zinc can aid in gastric tissue repair and prevent possible depletion. Consider cimetidine. Separate intake by at least 2 hours to avoid compromised gastric pH. Complement with low-dose copper with long-term use.
Loop diuretics ≈≈	Loop diuretics can increase urinary zinc excretion, but probably to a lesser degree than thiazide diuretics. Adverse effects from zinc administration unlikely. Further research warranted.	Consider concomitant zinc to prevent depletion. Watch for clinical signs of zinc depletion with extended diuretic therapy; lab tests often unreliable. Complement with low-dose copper with long-term use.
Metronidazole (vaginal) ⊕⊕	Combination of metronidazole and zinc may exert greater therapeutic activity in trichomoniasis than either agent alone. Adverse effects unlikely. Further research warranted.	Consider coadministration for synergistic effect, especially with recurrent trichomoniasis or compromised immune status.
Nonsteroidal anti-inflammatory drugs (NSAIDs) ◇◇/≈≈/⊕✗/⊕	NSAIDs and other anti-inflammatory agents may increase urinary zinc excretion and contribute to zinc depletion; NSAIDs may complex with zinc (and other metals) and decrease absorption and bioavailability of these substances. Many individuals with inflammatory conditions tend to have low zinc levels. Concomitant administration may provide enhanced therapeutic effects, but intake should be separated. Further research into potential synergy as well as possible nutrient depletion with long-term NSAID use warranted.	Consider concomitant zinc to prevent depletion and possibly enhance effects. Watch for clinical signs of zinc depletion with extended NSAID therapy; lab tests often unreliable. Separate intake by 2 or more hours. Complement with low-dose copper with long-term use.
Penicillamine ⊕⊕/⊕✗/◇◇/≈≈/✗	Penicillamine is a chelating agent applied to treat overload and intoxification involving copper, iron, and other metals. Zinc reduces copper levels by inducing intestinal cell metallothionein, which then forms a mucosal block, preventing copper absorption and increasing copper excretion in the stool. Concurrent use of penicillamine and zinc may enhance copper limitation and therapeutic outcomes in treatment of Wilson's disease. However, oral zinc intake may bind medication doses when ingested concurrently, reducing absorption of both agents. Penicillamine may deplete zinc, even with timing precautions. Further research warranted.	Consider concomitant zinc to enhance effects for reducing copper levels, with separated intake. Close supervision and monitoring necessary. Supplementation with multiple nutrients may be appropriate with extended therapy if depletion detected; separate intake by several hours.
Potassium-sparing diuretics ⊕✗/◇◇/≈≈	Potassium-sparing diuretics affect zinc in diverse ways. Amiloride may cause zinc accumulation by reducing urinary excretion, whereas triamterene may increase urinary zinc excretion in short term and may cause depletion with extended use. Amiloride is sometimes combined with thiazide diuretic to reduce zinc loss. Further investigation warranted into potential depletion effects with long-term use.	Consider concomitant zinc to prevent depletion and possibly enhance effects. Monitor for clinical signs of zinc depletion with any long-term diuretic therapy; lab tests often unreliable. Separate intake by 2 or more hours. Complement with low-dose copper with long-term use.
Radiotherapy ☼	Preceding or concurrent zinc may prevent or reduce loss or alteration of taste sensation and hasten recovery with radiation therapy to head and neck. Adverse effects unlikely. Further research warranted.	Consider concomitant zinc to prevent, mitigate, or reverse adverse effects on taste sensation.
Tetracycline antibiotics ◇◇/⊕✗/◇≈≈	Chelation between zinc and tetracycline-class antibiotics (other than doxycycline) and impaired absorption of both agents, to clinically significant degree, possible with concurrent intake. Zinc intake, even small amounts, could impair antimicrobial activity. General consensus despite minimal direct evidence. Zinc depletion possible with extended tetracycline use, but evidence lacking.	Discontinue zinc (including zinc-rich foods), or separate intake during short-term therapy. Consider doxycycline. Zinc supplementation may be appropriate with extended therapy, but caution warranted, even with established zinc depletion; separate intake by several hours.
Thiazide diuretics ≈≈	Thiazide diuretics can increase urinary zinc excretion, possibly causing clinically significant deficiency. Coadministration of amiloride may mitigate this adverse effect, whereas concurrent use of ACE inhibitor may exacerbate zinc loss.	Concomitant zinc may be appropriate if depletion occurs or deficiency develops. Monitor for clinical signs of zinc depletion with any long-term diuretic therapy; lab tests often unreliable. Complement with low-dose copper with long-term use.
Valproic acid Anticonvulsant medications (AEDs) ≈≈	Zinc may play a role in activity of anticonvulsants. Risk of decreased zinc levels is greater with VPA, alone or in combination with other anticonvulsant agents. Further, VPA can alter homeostasis of both zinc and copper and may cause depletion of either or both. Research into protective benefits of zinc coadministration limited, and further investigation warranted.	Concomitant zinc may be appropriate if depletion occurs or deficiency develops. Monitor for clinical signs of zinc depletion with any long-term AED therapy, especially VPA; lab tests often unreliable. Complement with low-dose copper with long-term use.
Warfarin Oral vitamin K antagonist anticoagulants ◇◇/✗✗/◇	Binding may occur with simultaneous intake and inhibit absorption and bioavailability of both agents. Decreased therapeutic activity probable with interaction; minimal effect with separation of intake. General consensus despite minimal direct evidence. Evidence on long-term effects lacking.	Concomitant zinc may be appropriate if depletion occurs or deficiency develops. Monitor for clinical signs of zinc depletion with any long-term AED therapy, especially VPA; lab tests often unreliable.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
		Complement with low-dose copper with long-term use.
Zidovudine (AZT) Nucleoside or nonnucleoside (analog) reverse-transcriptase inhibitors (NRTIs or NNRTIs) ≈≈/⊕⊕/⊕/✗/✗	Zinc is central to numerous immune functions, but AZT may deplete zinc levels. In addition, zinc deficiency may diminish drug effectiveness because zidovudine and other NRTIs require thymidine kinase, a zinc-dependent enzyme, for conversion to active triphosphate form. Moreover, HIV-infected populations tend to be zinc deficient. Conversely, elevated zinc status may not always be beneficial, and limited evidence suggests adverse effects in certain patients, especially at later stages of disease. Zinc coadministration appears to provide protective benefits, particularly in patients with diarrhea and opportunistic infections caused by *Pneumocystis carinii* and *Candida*. Further investigation warranted.	Concomitant zinc may be appropriate if depletion occurs or deficiency develops. Monitor for clinical signs of zinc depletion with any long-term HAART therapy, especially AZT; lab tests often unreliable. Complement with low-dose copper with long-term zinc use.

ADHD, Attention deficit–hyperactivity disorder; *GABA*, gamma-aminobutyric acid; *AED*, antiepileptic drug; *HIV*, human immunodeficiency virus; *HAART*, highly active antiretroviral therapy.

NUTRIENT DESCRIPTION

Chemistry and Forms

Zinc acetate, zinc arginate, zinc ascorbate, zinc aspartate, zinc carbonate, zinc citrate, zinc gluconate, zinc glycerate, zinc glycinate, zinc histidinate, zinc lactate, zinc methionate, zinc monomethionine, zinc oxide, zinc picolinate, zinc selenate, zinc sulfate, zinc undecylenate.

Physiology and Function

Zinc is required throughout the human body for protein synthesis, DNA synthesis, cell division, hormonal activity, neurotransmitter signaling, and other critical functions. Zinc's essential role in many biological processes is illustrated by its participation in the activity of up to 300 enzymes, in all known classes. Although its activity in immune function has often received the greatest attention, zinc is required for normal physiological functioning of most body systems, particularly growth and development, neurological function, and reproduction, as well as numerous catalytic, structural, and regulatory functions at the cellular level.

Absorption of zinc occurs both by carrier-mediated and energy-dependent saturable processes and by simple (nonsaturable) diffusion throughout the length of the small intestine, primarily in the jejunum. Absorption is regulated homeostatically, in a range of 2% to 70%, depending on concomitant intake and zinc status in healthy individuals, and is optimal at an intragastric pH of 3 or less because solubility of zinc salts is affected by pH.[1] Zinc is actively transported with albumin, amino acids, and an α_2-macroglobulin; transport is regulated, in part, by sulfur-containing amino acids. Bioavailability is mainly influenced by zinc status and form; however, red wine, soy protein, and glucose can enhance zinc absorption, and iron, copper, calcium, fiber, and phytates (a component of cereal grain fiber) can inhibit absorption. Elimination of zinc is primarily through the feces, with minor amounts excreted through the urine and perspiration.

The average adult human body contains a total of 1.4 to 2.5 grams of zinc, with 60% to 65% stored in skeletal muscle, 30% in bone, particularly marrow, and 4% to 6% in the skin. The brain (especially the hippocampus and cerebral cortex) is the organ with the highest zinc concentrations, with enzymatic zinc (85%-95%) and synaptic zinc constituting two separate pools of brain zinc. Zinc is also found in relatively high concentrations in the eye (particularly iris, macula of retina, and choroid), liver, spleen, pancreas, kidney, prostatic fluid, and spermatozoa. Both red blood cells (RBCs) and white blood cells (WBCs) contain relatively high concentrations of zinc.

Zinc is a cofactor in the synthesis of proteins, fats, and cholesterol, and as a metalloenzyme activator, zinc is associated with the activity of more enzymes than any other mineral. Carboxypeptidase is necessary for the digestion of dietary proteins. Several dehydrogenases require zinc, including alcohol, retinol, and sorbitol dehydrogenase. Carbonic anhydrase, a zinc enzyme, catalyzes the interconversion of carbon dioxide (CO_2) and bicarbonate (HCO_3^-) and thereby contributes to acid-base balance in RBCs. Cytochrome *c* is essential to electron transport and energy production. Superoxide dismutase (SOD), which contains both zinc and copper, inactivates free radicals in cytosol. Alkaline phosphatase (ALP) liberates inorganic phosphates for use in bone metabolism. The activity of these enzymes may be hampered by disruptions in zinc availability that are subclinical in degree (far short of frank deficiency) and conversely, are enhanced by increased zinc nutriture.

The immune, antioxidant, and detoxification systems require zinc, in ready availability and broad distribution, to maintain their functions at healthy levels. Immune function depends directly on zinc status in many ways through its central role in the production, regulation, activity, and equilibrium of both cellular and humoral immune responses, particularly as mediated by the thymus gland. Zinc participates in the regulation of a wide range of immune functions, including T lymphocytes, CD4 cells, natural killer (NK) T cells, interleukin-2 (IL-2), and SOD. As early manifestations of zinc deficiency, lymphopenia and thymic atrophy follow quickly on decreases in precursor T and B cells in the bone marrow, and IL-2 production by helper T (Th) lymphocytes will drop as lymphocyte proliferation decreases and cell-mediated immune function declines. Thus, decreases in available zinc may contribute to a premature transition from efficient Th1-dependent cellular immune activity to Th2-dependent humoral immune functions. The presence of adequate Zn^{2+} and nitrogen oxide tilt the thymic balance toward Th1 and IL-2 as nitrogen oxide releases Zn^{2+} from metallothionein, an intracellular storage molecule, and together they cooperate with glutathione (GSH) and GSSG, its oxidized form, to regulate immune responses to antigens. Conversely, a shift toward Th2 will be

characterized by elevations in levels of IL-4, IL-6, IL-10, leukotriene B_4 (LTB_4), and prostaglandin E_2 (PGE_2). Zinc is well known as a cofactor for SOD, a key antioxidant enzyme, but it also functions as a cofactor for alcohol metabolism and delta-6-desaturase (involved in PGE_1 synthesis). Among its activities in protecting against heavy metal toxicity, such as cadmium and lead, zinc's unique relationship with copper gives it a special capacity in countering toxic accumulation in Wilson's disease. Vitamin A levels are also regulated by a zinc-controlled release of hepatic stores.

Zinc plays diverse regulatory and support roles throughout the endocrine and reproductive systems as well as cell growth and differentiation processes. Proper functioning of genetic activities at many levels requires zinc, including the synthesis of DNA and RNA, protein synthesis, cellular division, and gene expression. Moreover, in its antioxidant capacity, zinc protects DNA from damage caused by oxidative stress. Zinc is necessary for the maturation of sperm, for ovulation, and for fertilization and normal fetal development. Zinc inhibits the activity of 5-alpha-reductase, the enzyme that irreversibly converts testosterone to dihydrotestosterone, a form that strongly binds to prostate tissue and thus contributes to hypertrophy. The hypogonadism observed in zinc deficiency may be related to impaired leptin secretion, which is also associated with zinc deficiency. Zinc promotes the conversion of thyroxine (T_4) to triiodothyronine (T_3) and enhances vitamin D activity. Thus, zinc plays a central role in normal growth and maturation, at cellular and systemic levels.

Synaptic zinc plays a modulatory role in synaptic neurotransmission. In the brain, zinc-containing neurons are found primarily in limbic and cerebrocortical systems. All neurons bearing synaptic zinc are glutamatergic. Synaptically released zinc plays a central role in brain excitability through modulation of ionic channels and amino acid receptors, including alpha-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid (AMPA), *N*-methyl-D-aspartate (NMDA), and gamma-aminobutyric acid (GABA) receptors. In particular, zinc acts as a potent antagonist of the glutamate-NMDA receptor. Zinc also induces *brain-derived neurotrophic factor* (BDNF) gene expression in the hippocampal/cortical neurons.[2] Anorexia, dysphoria, impaired learning, diminished cognitive function, and other behavioral disturbances and mood disorders, as well as some neurological disorders (e.g., epilepsy, Alzheimer's disease), can be associated with zinc depletion and alterations of brain zinc homeostasis.[3,4]

Zinc participates in the somatic interface with the environment through both the superficial tissues and the sensory organs. In addition to its presence in the skin and release through perspiration, the presence of zinc in the nails and hair is also notable (with deficiency indicated by leukonychia). Zinc's crucial role in skin health and wound healing is inherently related to its physiological and therapeutic activity in epithelial tissue. As mentioned, zinc is particularly concentrated in various components of the eye, where it is essential to dark adaptation and night vision. It also participates in the regulation of sensory perception through taste and smell. Not only is zinc crucial for taste perception, especially of salt, but taste response (or lack thereof) to zinc itself is predictive of deficiency status.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Proposed therapeutic and preventive uses of zinc range from the more common, and often self-prescribed, administration for prevention and mitigation of the common cold, treatment of acne and other dermatological conditions, enhancement of wound healing and immune response, to more clinical applications for high-risk mothers and malnourished infants, HIV and other viral infections, diminished fertility and reproductive gland function, gastric and bowel conditions, macular degeneration and other ophthalmologic diseases, and inflammatory processes such as rheumatoid arthritis. Notably, zinc administration can enhance muscular strength and endurance in healthy individuals, even in the absence of zinc deficiency.[5] Pharmacological doses of zinc are administered for the treatment of acrodermatitis enteropathica (clinical zinc deficiency caused by congenital zinc malabsorption), to ascertain level of zinc absorption, and Wilson's disease, to prevent the copper accumulation in tissues. Effective treatment of mild or moderate zinc depletion typically requires months of zinc administration to reverse, and severe zinc depletion can require a year or more to resolve in some cases.

Historical/Ethnomedicine Precedent

Recorded use of zinc dates back to Egypt, circa 2000 BCE, in the Western medical tradition. Known primarily for its use in skin lotions in both classical and folk traditions, its presence as zinc ore in calamine lotion is perhaps its most familiar form in recent popular memory and usage. *Zincum metallicum* and other forms of zinc were introduced into homeopathic medicine by Franz (1827), provings were conducted by Hahnemann (1839), and a large and systematic catalog of toxicology was assembled in the materia medica texts of Allen and others throughout the 1800s; these agents have been included in the official *Homeopathic Pharmacopeia of the United States* for more than 100 years. In the 1870s, W.H. Burt,[6] a highly respected homeopathic physician, wrote: "Zinc corresponds to diseases of the nervous system, the same as Iron does to diseases of the blood."

Although often selected because of their morphological similarity to male sexual organs (or "signature"), the recommendation of mussels (especially oysters and geoducks), seeds, and nuts as male tonics in many traditional systems of nutritional therapy may derive, at least in good part, from relatively high concentrations of zinc (and essential fatty acids). In pharmacognosy, the standard term for seed is *semen*, with both meanings related to substances rich in zinc.

Possible Uses

Acne vulgaris, acrodermatitis enteropathica, ageusia or hypogeusia (loss or diminishment of taste sensation), amenorrhea, anorexia nervosa, anosmia (lack of ability to smell), aphthous stomatitis (topical), athletic performance, attention deficit–hyperactivity disorder (ADHD), benign prostatic hyperplasia, birth defects (risk reduction), cataracts, celiac disease, cervical dysplasia, childhood intelligence (deficiency), cirrhosis (deficiency), common cold, contact dermatitis, Crohn's disease, cystic fibrosis, dermatitis herpetiformis (deficiency), diaper rash, diabetes mellitus (types 1 and 2), diarrhea (including with HIV), diverticulitis, Down syndrome, eczema, gastric ulcer healing, gastritis, halitosis, hepatitis, herpes simplex infection, HIV support, hypoglycemia, hypothyroidism, immune support/enhancement, infection, insulin resistance syndrome, lead and cadmium toxicity, macular degeneration, male infertility, male sexual function, minor injuries, night blindness, Osgood-Schlatter disease (with selenium), osteoarthritis, otitis media (recurrent), peptic ulcer, periodontal disease,

pharyngitis, psoriasis, radiation therapy support, rheumatoid arthritis, sickle cell anemia, skin ulcers, thalassemia (deficiency), ulcerative colitis, warts, Wilson's disease, wound healing (oral and topical).

Deficiency Symptoms

Primary (dietary) zinc deficiency in humans was first described in patients with alcoholic cirrhosis (in 1956) and then in rural Iranian children and Iranian and Egyptian farmers with inadequate nutritional intake in the early 1960s. Primary deficiency has largely been considered a significant risk in individuals and populations with malnourishment or compromised physiology. However, awareness continues to grow as to the full extent of at-risk populations from a broad range of age groups, socioeconomic conditions, and living situations. Foods grown in nutrient-depleted soil and processed foods are often low in zinc. In addition to protein/calorie-restricted diets, potential deficiencies from diets replete with zinc-poor foods but limited in foods rich in highly bioavailable zinc are often aggravated by foods that are rich in inhibitors of zinc absorption. Infants, impoverished and elderly persons with poor nutritional status, and those consuming excessive alcohol or with renal and hepatic disease are clearly susceptible, but seemingly healthy individuals with unbalanced nutritional intakes, elevated demands, or adverse genetic characteristics may be equally at risk. Survey data indicate that more than 60% of adults (≥20 years) in the United States do not consume dietary zinc at the level of the recommended dietary allowance (RDA). Even by following the U.S. Department of Agriculture (USDA) food pyramid recommendations of the past several decades, an individual will not obtain adequate zinc intake on a daily basis. Moreover, some young women who avoid red meat contribute, at least in part, to their being both zinc and iron deficient. Thus, the typical diet in developed countries usually provides insufficient zinc for healthy function, with infants, adolescents, women, and the elderly at greater risk.[7-10] The prevalence of primary zinc deficiency is estimated at 25% to 49% of the world's population.[11,12]

Mild zinc deficiency is fairly common and can have a significant and pervasive impact within a short time. The supply of zinc within the human body operates with a small margin of error relative to metabolic needs. The very small amount of zinc that functions as the "exchangeable zinc pool" in the human body is sufficient for only a few days without intake. Even with the relative inaccessibility of zinc deposits in bone or muscle tissue, excess zinc intake in the short-term is not usually retained (because of decreased absorption or rapid excretion). Consequently, consistent zinc intake is essential to maintain zinc metabolism within the narrow parameters between healthy function and systemic repercussions of insufficiency. Thus, a zinc-poor diet, poor assimilation, interfering agents, and an increase in physiologic demands can result in adverse effects within a short period. Nevertheless, scientific knowledge of the pathogenic mechanisms and complete characteristics of zinc deficiency remain incomplete.

A wide range of conditions can contribute to compromised zinc nutriture, insufficiency, and conditioned (secondary) deficiency. *Acrodermatitis enteropathica* is an inherited (autosomal recessive) disease characterized by zinc malabsorption and resulting in eczematoid skin lesions, alopecia, diarrhea, and concurrent bacterial and yeast infections. The life stages characterized by rapid growth, particularly pregnancy and lactation, childhood, and adolescence, are potentially as vulnerable as the hospitalized or institutionalized elderly person. Multiple pregnancies or shifts in growth rate, as well as infection or malignancy, can further aggravate disequilibrium in zinc metabolism. Likewise, deficient zinc intake can occur with chronic dieting, as well as poorly planned vegan, vegetarian, and semivegetarian diets. Excessive iron, calcium, or grain intake, particularly with simultaneous ingestion, may also interfere with zinc absorption, particularly because of phytic acid content of cereal grains. Impaired zinc absorption also occurs in individuals with gastrointestinal (GI) disorders, including diarrhea, pancreatic insufficiency, celiac sprue or other malabsorption syndromes, inflammatory bowel disease, Crohn's disease, and ulcerative colitis. Likewise, injuries or inflammatory conditions, such as burns, wound healing, dermatitis, rheumatoid arthritis, and chronic inflammatory diseases, that increase interleukin-1 (IL-1) can rapidly deplete available zinc due to increased utilization, thus producing short-term adverse effects. Hemorrhage, hemolytic anemias (e.g., sickle cell disease, thalassemia), superficial losses, excessive diuresis, or GI tract wastage into stool can also produce rapid zinc loss sufficient to cause systemic problems. Renal insufficiency predisposes to excess zinc excretion. Macular degeneration, type 2 diabetes mellitus, malignant melanoma, congestive heart failure, and other degenerative conditions are also associated with zinc deficiency. The variety of conditions that can adversely affect zinc status, together with the delicate balance of zinc available within the human organism, render zinc nutriture critical and the consequences of deficiencies pervasive and potentially significant.

The classic clinical presentation of severe zinc deficiency is characterized by diarrhea, poor wound or ulcer healing, dermatitis, psychiatric disturbances, weight loss, intercurrent or recurrent infection, alopecia, and hypogonadism (in males). Immunodepression, muscle pain, and fatigue are also among the first and most important signs and symptoms of zinc deficiency, and immune function can be depressed in humans with even mild zinc deficiency. In general, any rapidly growing cells can be affected in initial stages. Thus, compromised health of epithelial tissues, manifesting as impaired wound healing, dermatitis, rough skin, inflammatory acne, poor nail health, increased incidence of infections, diminished immune response, and elevated intolerance to environmental toxins may also indicate impaired zinc status. Anosmia and reduced taste acuity can also suggest zinc deficiency and may manifest only through poor appetite. Photophobia, night blindness, nystagmus, or decline in visual acuity may signal diminished zinc availability affecting the eyes, resulting, at least in part, from decreased ability to mobilize retinol from the liver. Diminished fertility, particularly with impaired spermatogenesis or ovulation, menstrual irregularities, weight loss, impaired glucose tolerance, and increased lipid peroxidation are among the predictable but often-unrecognized consequences of deficiencies in physiological functions dependent on zinc nutriture. Also less obvious, but more insidious in outcomes, are longer-term changes that can result from poor zinc status, such as slow or stunted growth and delayed puberty or other sexual development, as well as irritability, anxiety, depression, difficulty with concentration and cognitive function, impaired learning, or other psychoneurological conditions. Zinc deficiency before and during pregnancy may contribute to intrauterine growth retardation and congenital fetal abnormalities. In rat studies, zinc deficiency during pregnancy results in lifelong immune abnormalities in the offspring despite adequate zinc intake from birth, which requires three generations of normal zinc nutriture to reverse.[13]

Dietary Sources

Seafood and red meat (especially liver and other organ meats) are the richest dietary sources of zinc, with a single oyster providing about 8 to 15 mg zinc. Poultry and eggs provide moderate amounts of dietary sources of zinc. Whole grains, nuts, and seeds provide smaller amounts of zinc, ranging from 0.2 to about 3 mg per serving, with notable sources being sunflower and squash seeds, wheat germ, hard-wheat berries, wheat bran, buckwheat, rice bran, millet, whole-wheat flour, oatmeal, brown rice, cornmeal, and sprouted grains. However, the zinc in plant foods, particularly whole-grain cereals and soy protein, can bind to phytic acid to form an insoluble zinc-phytate complex and thus is usually less bioavailable. Breads, breakfast cereals, and nutrition bars are often fortified with substantial amounts of zinc. Other food sources of zinc include hard cheese, peanuts, soy meal, black-eyed peas, green beans, chickpeas, lima beans, spinach, green onion, and green leafy vegetables. In general, food processing removes or destroys a high proportion of zinc, as well as other trace elements. The presence of certain amino acids, such as cysteine and histidine, may enhance absorption of zinc from foods.

Nutrient Preparations Available

Numerous forms of zinc are available, as previously listed. Zinc sulfate is an inexpensive form most often used in clinical trials. Many experienced practitioners of nutritional therapeutics, however, prefer to administer organically bound or chelated forms (e.g., zinc acetate, zinc citrate, gluconate, zinc glycerate, zinc monomethionine, zinc orotate, zinc picolinate, zinc-protein hydrolysate), based on a lower incidence of gastric irritation and (presumed) superior bioavailability and utilization. In general, zinc acetate provides the most bioavailable form of zinc, across a broad range of gastric pH.

Lozenges generally contain zinc gluconate, zinc gluconate-glycinate, or zinc acetate. The efficacy of various lozenges correlates with their relative *iZn* dosage, the sum of all positively charged *(ionized)* zinc species for zinc compounds at physiologic pH of 7.4.[14] Although all others forms are available over the counter (OTC) as nutritional supplements, zinc acetate is considered a prescription item because of its use in the treatment of Wilson's disease, although zinc acetate lozenges are available as an OTC drug for upper respiratory infection (URI) treatment.

The various forms of oral zinc are salts with differing zinc content. For example, zinc sulfate contains 23% elemental zinc and zinc gluconate 14.3% elemental zinc. Thus, the amount of zinc in some typical supplemental forms is as follows: zinc amino acid chelate, 100 mg/g; zinc gluconate, 130 mg/g; zinc orotate, 170 mg/g; and zinc sulfate, 227 mg/g. A typical zinc sulfate dose of 220 mg provides approximately 55 mg of elemental zinc. However, solubility and ionizability of the various salts of can have major impact on bioavailability.

Dosage Forms Available

Capsule, injectable, intranasal gel, intranasal spray, liquid, lozenge, tablet, topical. Parenterally, zinc is usually included as a component of total parenteral nutrition (TPN).

For optimal absorption, oral zinc should usually be ingested between meals. However, if adverse GI effects occur, consumption with meals may be adequate and effective. In general, oral zinc intake should be separated from ingestion of high-fiber foods to minimize impairment of absorption, as well as high-dose calcium or iron supplements. Likewise, the antiviral activity of zinc lozenges may be impaired by certain flavorings, sweeteners, or other additives.

Source Materials for Nutrient Preparations

Zinc acetate and zinc chloride are derived from mineral salts consisting of zinc and chloride or zinc nitrate and acetic anhydride, respectively. Zinc carbonate is derived from smithsonite or zincspar. Chelates such as zinc citrate, zinc gluconate, zinc lactate, zinc orotate, zinc picolinate, and zinc selenate are derived from smithsonite or other rock processed with citric acid, gluconic acid, lactic acid, orotic acid, picolinic acid, or selenic acid, respectively. Zinc oxide is derived from zincite and zinc phosphate from hopeite.

Dosage Range

The issue of zinc dosage is unclear and eludes scientific knowledge necessary to establish a basis for widely agreed conclusions. Dietary supplements typically contain 5 to 50 mg (elemental zinc) per daily dose. Moderate intake of 15 to 50 mg daily can be used safely to provide for physiological requirements and prevent deficiency. Short-term, repeated use of zinc lozenges containing higher doses (e.g., 13-25 mg each), with up to 10 lozenges daily, is generally well tolerated for several-day periods. Therapeutic application of zinc at 50 mg, one to three times daily, may be appropriate for certain conditions, such as copper overload in Wilson's disease, under the supervision of a health care professional. The presence of zinc in some fortified foods may alter the equation for any given individual based on consumption, but is often offset by impaired bioavailability resulting from certain dietary constituents and how they affect certain forms of zinc.

Adult

Dietary: The U.S. RDA for zinc is 15 mg per day for adult men and 12 mg per day for adult women, but average daily intake in developed societies is typically only 60% to 70% of that amount, with the average adult daily diet in the United Kingdom providing 11.7 mg for men and 8.7 mg for women. The official U.S. recommendations for daily intake in pregnant women is 11 mg (13 mg if ≤18 years old) and 12 mg for nursing women (14 mg if ≤18 years old).

Supplemental/Maintenance: 15 to 50 mg per day, preferably with copper.

In some respects, however, zinc intake beyond adequate dietary intake is sometimes considered inappropriate unless indicated, given "almost no gap for supplementation" above the RDA and the reference dose (RfD) for safe intake of zinc, although, as noted, usually a gap exists between average daily dietary intake and the recommended daily intake.[12] Few data are available on optimal zinc intakes (as assessed by function of zinc-dependent enzymes in free-living human subjects), and it is likely that optimal intakes vary considerably depending on age, lifestyle, and various states of health and disease.

Pharmacological/Therapeutic: 50 to 350 mg (elemental zinc) per day.

Oral doses as high as 220 mg zinc sulfate three times daily have been used in trials of zinc for the prevention of crisis in sickle cell anemia, and twice daily for 12 weeks to correct zinc deficiency in cirrhotic patients with symptoms of deficiency (e.g., blunted taste/smell).[15,16] In a trial involving patients with chronic fatigue syndrome, 135 mg/day was administered for 15 days (along with 2 mg copper daily) to correct zinc deficiency.[17]

Toxic: Toxicity can occur at levels as low as 60 mg/day (with prolonged intake) but is more frequently associated with doses higher than 300 mg/day. Prolonged intake at doses higher than 150 mg/day may be associated with adverse effects. The official U.S. tolerable upper limit (UL) for adults (≥19 years) is 40 mg, including pregnant or nursing women, although it is 34 mg/day if such women are 18 years old or younger.[18] This amount includes dietary intake and thus may vary considerably with high consumption of fortified foods or foods naturally rich in zinc.

Pediatric (<18 Years)

Dietary: Zinc concentrations in breast milk are relatively low, but such zinc is highly absorbable. Official U.S. recommendations for daily intake follow[18]:

Infants, birth to 6 months: 2 mg/day
Infants, 7 to 12 months: 3 mg/day
Children, 1 to 3 years: 3 mg/day
Children, 4 to 8 years: 5 mg/day
Children, 9 to 13 years: 8 mg/day
Adolescents, 14 to 18 years: 9 mg/day for females; 11 mg/day for males

Clinical experience with adolescents suggests that much larger amounts may be required during growth spurts (up to 40 mg/day).
Supplemental/Maintenance: Usually not recommended for children under 12 years of age with healthy, balanced diet, without excessive dietary phytates.
Pharmacological/Therapeutic: 5 to 40 mg per day, for specified periods.

Trials investigating zinc supplementation in infants born small for gestational age (SGA) typically use 5 mg zinc sulfate daily, often combined with other nutrients.[19] Zinc acetate (10 mg twice daily for 5 days) has been used successfully in infants and young children with severe acute lower respiratory infection.[20] Several prominent trials have found efficacy of low-dose oral zinc in acute and persistent diarrhea in children under 5 years of age in developing countries.
Toxic: 150 mg/day on a chronic basis, or acutely with doses greater than 200 mg daily. However, the toxic dose of zinc depends primarily on dose and duration, and also varies with status and absorption, weight, and concomitant intake. Single intravenous (IV) doses of 1 to 2 mg zinc/kg body weight have been given to adult leukemia patients without toxic manifestations. Consensus as to toxic dose in clinical applications has not been established, and plasma levels sufficient to produce symptoms of toxic manifestations are not known.
Tolerable upper intake levels (UL) for zinc follow[18]:

Infants, 0 to 6 months: 4 mg/day
Infants, 7 to 12 months: 5 mg/day
Children, 1 to 3 years: 7 mg/day
Children, 4 to 8 years: 12 mg/day
Children, 9 to 13 years: 23 mg/day
Adolescents, 14 to 18 years: 34 mg/day

Laboratory Values

Overview

Clinicians and researchers broadly agree that clinical presentation and response to zinc administration provide the most accurate means of assessing zinc status and confirming deficiency status. Thereafter, retesting (e.g., plasma zinc) and reevaluation of symptoms after 4 to 6 months of treatment are usually effective for determining if dosages need adjustment. In a review, Hambridge[21] (2003) concluded that there is a "compelling demand for improved zinc biomarkers" based on numerous characteristics peculiar to the physiology of zinc in the human organism. "More specific markers of zinc status are needed, and their relationships to zinc-dependent cellular functions and the distribution and allocation of zinc to the different organ systems need to be clarified." Some physicians experienced in nutritional therapeutics consider measuring the leukocyte zinc level as the best laboratory method for determining zinc status.[22] Most clinicians and researchers do not consider hair a reliable form of analysis for measuring tissue levels of zinc.[23] Moreover, some clinicians observe that urine and hair tissue levels are often elevated in patients with zinc deficiency because of dysfunction in zinc metabolism and high rates of excretion.

Erythrocyte Zinc

Most of the zinc measured as erythrocyte zinc is incorporated in carbonic anhydrase. Although some studies report detection of depletion through low levels, erythrocyte zinc has been generally regarded as not readily depleted and therefore not accurately indicative of zinc status.[24]

Hair Zinc

Some clinicians have suggested that analysis of hair zinc concentrations might reveal associations between low hair zinc levels and zinc depletion status. However, numerous factors, such as age, growth rate, and dietary intake of phytates and meat, can confound analysis and decrease this test's ability to consistently determine impaired zinc status or inadequate intake.[23,25-29] Antidandruff shampoos often incorporate zinc as well, which can greatly elevate hair zinc levels.

Plasma Zinc

The range for normal plasma levels for zinc is 58 to 106 μg/dL. In blood plasma, zinc is bound to albumin (80%) and to α_2-macroglobulin (20%). Plasma zinc levels appear to follow a circadian rhythm, with the highest values occurring late morning, at approximately 10 AM. Plasma zinc can be normal even when plasma albumin is low, because albumin normally contains many unsaturated binding sites.

Plasma zinc and serum zinc are often used in clinical and research settings but are physiologically insensitive and of limited diagnostic value. Hambridge[21] observed: "Plasma zinc is currently the most widely used and accepted biomarker of zinc status despite poor sensitivity and imperfect specificity . . . . One reason that plasma zinc does not accurately reflect the volatile relationship between zinc intake and absorption is that homeostatic control of plasma zinc concentrations can occur while moderate changes are occurring in the zinc content of one or more of the pools of zinc that exchange rapidly with zinc in plasma." Furthermore, the decline that occurs as a recognized component of the acute-phase response in infections represents at least one important limitation affecting the specificity of plasma zinc as an index of zinc status.[30,31] Severe acute zinc deficiency states, such as untreated acrodermatitis enteropathica, may reveal profoundly depressed plasma zinc levels. However, mild zinc deficiencies that can adversely affect physiological function may appear as plasma zinc concentrations within the normal range, as with growth-limiting zinc deficiency states in young children.[26] Various studies have conflicting findings and mixed conclusions regarding an association between zinc intake and plasma zinc.

Nevertheless, concentrations less than 70 μg zinc/dL plasma can serve as a useful predictor of growth response to zinc supplementation, and beneficial effects of zinc administration in the prevention and management of diarrhea can be predicted using lower cutoff values. Plasma levels less than 70 μg/dL might constitute a better definition of deficiency state.

Red Cell Membrane Zinc

Metallothionein levels in erythrocytes respond to administration of zinc as well as restricted dietary intake.[32] Thus, RBC membrane zinc may be a sensitive indicator of zinc depletion, but its practical implementation on a widespread basis is considered unlikely given the complexity of sample preparation. A parallel situation appears with monocyte, neutrophil, or platelet zinc.[33-36]

Serum Zinc

Serum zinc concentration less than 33 μg/dL indicates zinc deficiency. Serum levels 33 to 50 μg/dL indicate marginal zinc status. The normal range for serum zinc is 67 to 124 μg/dL, although this varies between clinical laboratories.

Serum zinc is considered an insensitive marker of physiological zinc status, for the same reasons previously stated in relationship to plasma zinc.

White Blood Cell Zinc

The levels of zinc in leukocytes or lymphocytes appears to reflect zinc status accurately, particularly in relation to key zinc-related functions such as immune function, life stage, and growth processes. For example, leukocyte (WBC) zinc is reflective of fetal growth and associated with maternal muscle zinc concentration. Likewise, activity of lymphocyte ecto-5'-nucleotidase is a sensitive indicator of zinc status.[12,37-41]

Assessment of gene expression of zinc-dependent genes in lymphocytes (specifically cellular zinc transporter hZip1) offers promise as a biomarker of expression of the cellular zinc response to zinc intake and bioassay for zinc status.[42]

Zinc Tally

In this quick and simple screening method for evaluating zinc status, the absence of the typical metallic taste of zinc, after placing 2 teaspoons of a 0.1% solution of zinc sulfate heptahydrate in the patient's mouth and holding it there for 10 seconds, suggests deficiency. An immediate taste perception indicates that zinc status may be adequate; conversely, lack of zinc taste suggests deficiency.

Zinc Tolerance Test

In this test an oral load of 50 mg elemental zinc is administered, after a baseline plasma zinc measurement, and plasma zinc is remeasured 120 minutes later. A twofold to threefold increase in plasma zinc indicates zinc deficiency. Zinc supplements need to be avoided for 24 hours before sampling of plasma.

CD4+/CD8+ T-Lymphocyte Ratio and Thymulin Activity

The CD4+/CD8+ T-lymphocyte ratio and thymulin activity have been advanced as potential immunological tests for zinc deficiency, but evidence confirming their accuracy is lacking.

Other findings possibly consistent with zinc insufficiency, but also resulting from other causes, include the following[43]:

- Elevated anserine and carnosine peptides, with low levels of essential amino acids, in urine or plasma amino acid analysis.
- Elevated phosphoserine and phosphoethanolamine in urine amino acid analysis.
- Elevated lactic acid in plasma or urine (lactic acid dehydrogenase also is zinc dependent).
- Elevated or normal linolenic acid, but low gamma-linolenic acid, consistent with weak delta-6-desaturase activity (zinc dependent).

SAFETY PROFILE

Overview

Zinc dosage beyond the RDA is not established, and the perpetually marginal nature of zinc nutriture leaves a relatively small dosage range and tight time frame for safe and effective use of zinc between suboptimal and potentially toxic intake levels, particularly with extended use outside a balanced nutrient regimen. The affinity of zinc for certain tissues appears to result in a pattern of benefit and toxicity converging (e.g., immune system, possibly prostate). The dose typically used for short-term immune stimulation as a lozenge (13-25 mg each) would be excessive for continued use with oral intake and could impair immune function (at >150-300 mg/day). Likewise, 25 to 30 mg daily has been used to improve pregnancy outcomes in low-income pregnant women and pregnant teenagers, but a significantly higher dose could have potentially adverse effects during pregnancy, especially on embryogenesis.

Zinc is perhaps the least toxic mineral nutrient at usual doses but can be strikingly toxic at very high doses associated with industrial exposure. Notably, major authorities on zinc physiology, requirements, and safety acknowledge the limited scope of scientific knowledge as to its physiological functions, the multiple variables affecting bioavailability, dynamic relationships between zinc and other minerals, parameters governing insufficiency and toxicity, and methods of assessing functional zinc levels.

Nutrient Adverse Effects

General Adverse Effects

Zinc is generally considered relatively nontoxic at low to moderate levels typical of supplemental use: less than 50 mg elemental per day. Given the narrow gap between potentially insufficient and excessive levels, both deficiency and toxicity can vary significantly among individuals based on tissue and circulating levels, historic intake, zinc pool status, recent or active infection, blood loss or other depletion factors, dietary interactions, and other variables. Gastrointestinal upset and nausea are quite common when zinc supplements, especially zinc sulfate, are taken on an empty stomach. More importantly, zinc administration, especially lacking in compensatory copper support, can produce adverse effects rapidly (as with deficiency), which grow in intensity based on dose and duration and influenced by other variables. The primary toxic effects of zinc, typically associated with prolonged intake at levels greater than 150 mg daily, include copper deficiency anemia, depressed immune function, and reduced high-density lipoprotein (HDL) cholesterol levels.

Topical zinc preparations are generally considered safe and unlikely to produce any adverse effects. However, anosmia has been reported with zinc nasal spray and in rare cases has been reported to be severe or permanent.[44]

The primary effects of zinc toxicity can occur with doses higher than 150 mg/day on a chronic basis or acutely with doses greater than 200 mg daily. They include diarrhea, nausea, vomiting, metallic taste in the mouth, dizziness, drowsiness, incoordination, and lethargy. Gastric erosion and hematuria with chronic high-dose use have been reported but not confirmed. Ingestion of 10 to 30 g of zinc sulfate can be lethal

in adults. However, acute zinc toxicity is extremely rare because ingestion of the amounts required for toxicity symptoms (2 g/kg) will usually provoke vomiting before toxic dose levels are attained. Impairment of copper absorption can begin at daily doses as low as 50 mg elemental zinc, with copper depletion accruing over time and manifesting as low serum copper and ceruloplasmin levels, microcytic anemia, and neutropenia; iron deficiency is also possible. Immune function can become impaired, HDL cholesterol levels decrease, and total cholesterol levels increase with daily doses over 300 mg/day for extended periods, but possibly as low as 150 mg/day, perhaps as a result of induced copper deficiency.[45–49] Subsequently, zinc-induced copper deficiency has been associated with cases of reversible acquired sideroblastic anemia, cardiac arrhythmias, and bone marrow depression. Such reports have involved chronic intake of 450 to 1600 mg daily, and many such cases are properly characterized as zinc abuse, with ingestion of coins being the source of zinc in one individual.[50–55] Inhalation of zinc oxide in certain industrial settings and the use of galvanized pipes for drinking water are also known causes of excess zinc exposure.

Short-term frequent use of zinc lozenges can occasionally produce digestive upset, local oral irritation, and unpleasant taste; typically reversible with cessation.[49,56]

Adverse Effects Among Specific Populations

One study from India suggests that the concomitant use of zinc and oral antibiotics in the acute management of pneumonia of infants or children may delay recovery during the hot season, particularly in the absence of zinc deficiency.[57]

Two preliminary papers by Bush et al.[58,59] discussed the possibility of zinc aggravating amyloid formation in individuals with Alzheimer's disease. However, subsequent research articles and reviews have concluded that zinc does not cause or exacerbate Alzheimer's disease symptoms, and may enhance mental function by improving platelet membrane microviscosity.[60,61]

Genotoxicity

"Zinc is apparently neither a mutagen nor a carcinogen."[12,62] However, in one study analyzing data from a larger trial, researchers reported a slight increase in the relative risk of prostate cancer among men who used zinc supplements for more than 10 years, particularly at doses greater than 100 mg elemental zinc daily.[63]

Pregnancy and Nursing

Maternal nutritional zinc deficit "can have permanent negative effects on the growth of offspring," and zinc administration at typical dose levels may be beneficial during pregnancy. However, excess zinc intake "during embryogenesis can be teratogenic or lethal," and premature birth and stillbirth have been reported when women consumed 100 mg three times daily during the third trimester.[12,62,64] The use of supplemental zinc by nursing mothers over an extended period, without compensatory copper support, could contribute to zinc-induced copper deficiency in breastfed infants. Nevertheless, no reports or studies in the scientific literature show any adverse effects on fetal development from supplemental zinc, at typical doses, in well-nourished mothers or in infants who are breastfed.

Contraindications

No contraindications have been established for zinc.

Precautions and Warnings

Extended use of zinc without copper carries a warning. The recommended ratio of zinc to copper is 15:1 to 20:1. This ratio is higher in elderly persons, who, in the United States, tend to have high copper levels and low zinc levels because of a history of chronic ingestion of water carried through copper pipes.

INTERACTIONS REVIEW

Strategic Considerations

Three simple and consistent themes are recurrent among the various interactions between zinc and pharmacological agents. First, as a mineral/metal, zinc tends to chelate with many substances when ingested simultaneously or in temporal proximity. This potential problem is easily avoided through patient education and clinical management; individuals should separate intake, preferably taking zinc at least 2 hours before or 4 hours after such medications. Second, in all situations except the treatment of individuals with Wilson's disease, the default prudent measure with any long-term application of zinc is to avoid zinc-induced copper deficiency by periodically monitoring serum copper levels and coadministering low-dose copper (1-3 mg/day). Third, within the human organism, zinc is volatile with an ever-shifting distribution between pools. Thus, establishing zinc deficiency or monitoring the impact of any agent on functional zinc status is difficult and unreliable. Consequently, at usual dosage levels and with attentiveness to clinical manifestations of zinc deficiency (or excess), coadministration of zinc within a therapeutic strategy carries minimal risk of adverse interactions, other than copper depletion and the predictable chelation phenomena common to most minerals when ingested with other substances.

Numerous pharmaceutical agents are associated with adverse effects, both subtle and overt, of zinc depletion. Consequently, numerous clinical situations occur in which coadministration of zinc may improve zinc nutriture, related physiological functions, and clinical manifestations, even when prior conventional laboratory assessment had revealed no measurable signs of depletion, insufficiency, or deficiency. These recurrent patterns indicate two probable phenomena: zinc can provide benefit in the absence of depletion, detected or not, and conventional laboratory methods currently applied for assessing zinc status are insensitive and inadequate to clinical demands. Our limited knowledge of the many functions of zinc is repeatedly revealed in the sparsity and limited depth of both the observations of zinc-related benefits and interactions and the mechanisms involved.

Many widely used pharmaceutical agents contribute to zinc depletion, usually through binding and increased urinary zinc excretion. Thus, coadministration of zinc may reduce depletion effects or prevent other adverse effects associated with a wide range of medications used to treat hypertension, inflammation, and other conditions. Particularly with chronic use, thiazide diuretics increase urinary zinc excretion, as do loop diuretics, although probably to a lesser degree. Although patients treated with angiotensin-converting enzyme (ACE) inhibitors (especially captopril) at clearly are risk for zinc depletion, the effects of potassium-sparing diuretics on zinc are diverse and complicated. Furthermore, amiloride is often combined with a thiazide diuretic to reduce mineral loss, but amiloride may cause zinc accumulation by reducing urinary excretion. In contrast, triamterene can increase urinary zinc excretion in the short-term and cause depletion with extended use. In patients treated with antacids and gastric acid–suppressive medications,

long-term drug therapy can impair zinc absorption and reduce availability by interfering with the normal acid environment of the stomach; although cimetidine appears to be an exception among H_2 blockers. With these drugs, administration of zinc can prevent or reverse depletion and enhance healing of gastric tissue damaged by ulceration. When coadministered with nonsteroidal anti-inflammatory drugs (NSAIDs), zinc may reduce risk of adverse effects on zinc status while providing protective effects and contributing to enhanced therapeutic outcomes.

Oral corticosteroids and valproic acid, alone or in combination with other anticonvulsant agents, represent examples of medications that can deplete zinc, but for which evidence of benefit from concomitant zinc is limited or lacking.

Evidence of variable strength suggests a probable synergy or other benefit from concomitant zinc administration with a wide range of conventional interventions, including mixed amphetamines, androgens, clobetasol (and potentially other topical corticosteroids), metronidazole (in treating trichomoniasis), and chlorhexidine-zinc oral rinse. In the treatment of individuals with Wilson's disease, concomitant zinc may enhance the therapeutic activity of penicillamine in reducing copper levels, although intake needs to be separated. Zinc therapy can be applied to reduce adverse effects to taste sensation in patients receiving radiation therapy, particularly to the head and neck.

In several areas the coadministration of zinc with conventional therapies appears to produce mixed effects, depending on patient characteristics, with full implications as yet unclear. For example, in women of reproductive age, oral contraceptives may decrease serum levels of zinc; conversely, osteoporotic postmenopausal women taking conjugated estrogens and medroxyprogesterone may exhibit reductions in previously elevated urinary zinc excretion. Zidovudine (AZT) and related antiretroviral agents present another complicated situation where divergent responses are common. In a patient population often characterized by zinc insufficiency, zinc coadministration may reduce drug-related adverse effects, add protective benefits (particularly in patients with diarrhea and opportunistic infections), provide no significant benefit, or even potentially elevate the risk of complications.

Numerous clinical situations allow for possible synergy, particularly in individuals or populations at greater risk for compromised zinc or broader nutritional status. The areas of antibiotic therapy, oral or topical, and antidepressant medications, particularly tricyclic and selective serotonin reuptake inhibitor (SSRI) antidepressants, offer significant potential for continued research into integrative therapeutic applications.

In many situations, zinc (as well as most other minerals) tends to bind with other substances and thereby decrease bioavailability and therapeutic action or nutritive value of both agents. Separation of intake remediates this problem. Antibiotics from the tetracycline class (other than doxycycline) or fluoroquinolone class (particularly ciprofloxacin) and warfarin or related oral vitamin K antagonist anticoagulants stand as primary examples of situations commonly accepted as involving a significant risk of pharmacokinetic interference.

Zinc may play a central role in the intimate relationships between the immune system and the mental-emotional states traditionally ascribed to the central nervous system (CNS). The body of scientific knowledge emerging within the field of psychoneuroimmunology may render obsolete conventional parsing of academic disciplines, which often are inadequate in conveying the totality of complex physiological functioning inherent in clinical medicine. A more comprehensive model can provide a forum for further research into the broader functions of zinc that transcend narrow categorization and defy reductionist analysis.

NUTRIENT-DRUG INTERACTIONS

Amphetamines and Related Stimulant Medications

Amphetamine (amphetamine aspartate monohydrate, amphetamine sulfate), dextroamphetamine (dextroamphetamine saccharate, dextroamphetamine sulfate; D-amphetamine; Dexedrine).
Mixed amphetamines: amphetamine and dextroamphetamine (Adderall; dexamphetamine).
Extrapolated, based on similar properties: Methylphenidate (Metadate, Methylin, Ritalin, Ritalin-SR; Concerta).

Interaction Type and Significance

◉ **Emerging**

Effect and Mechanism of Action

Zinc nutriture and physiology are important in mood and brain function and may play an independent role in physiology related to attention deficit–hyperactivity disorder (ADHD), particularly in individuals of older age and higher weight with low zinc and free fatty acids levels. Mechanisms apart from correcting zinc deficiency have not been investigated or elucidated. However, data derived from research into depression and CNS function are relevant. In particular, zinc plays an important role in neurotransmission in the brain by modulating the activity of glutamate and gamma-aminobutyric acid (GABA) receptors.[65] Furthermore, hippocampal and cortical neurons, noted for high concentrations of zinc, "possess mechanisms for Zn^{2+} uptake and storage in synaptic terminals" and for stimulation of release of Zn^{2+} ions along with neurotransmitters. "Zn^{2+} modulates predominantly the excitatory (glutamatergic) and inhibitory (GABA-ergic) amino acid neurotransmission pathways in CNS."[66]

Research

Limited research suggests that zinc may provide independent benefit in patients with ADHD and may complement conventional therapy using mixed-amphetamine salts. Studies have suggested a correlation between zinc deficiency and pathophysiology of ADHD.[67-69] In a double-blind, placebo-controlled study involving 400 children (72 girls, 328 boys, mean age 9.61 years), Bilici et al.[70] found that zinc sulfate (150 mg daily for 12 weeks) was "significantly superior to placebo in reducing symptoms of hyperactivity, impulsivity and impaired socialization in patients with ADHD. However, full therapeutic response rates of the zinc and placebo groups remained 28.7% and 20%, respectively." The authors added that "the hyperactivity, impulsivity and socialization scores displayed significant decrease in patients of older age and high BMI score with low zinc and free fatty acids (FFA) levels."[70] In a paper published later that same year (2004), Akhondzadeh et al.[71] reported findings from a 6-week, double-blind, randomized trial involving 44 children (26 boys and 18 girls), age 5 to 11 years, comparing methylphenidate (1 mg/kg/day) plus zinc sulfate (15 mg elemental zinc daily) to methylphenidate

plus placebo in the treatment of ADHD. Outcomes, as assessed using Parent and Teacher ADHD Rating Scale scores, "improved with zinc sulfate," and the difference between the two protocols was significant, "as indicated by the effect on the group, the between-subjects factor." The difference in frequency of adverse effects between the two groups was "not significant." The authors concluded that their findings demonstrated that zinc coadministration "might be beneficial in the treatment" of children with ADHD, and that further investigations using different doses of zinc are required to replicate these findings.[71]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating individuals diagnosed with ADHD are advised to consider nutritional support independently or in concert with the pharmacological therapies, such as methylphenidate or mixed amphetamines. The evidence for benefit from zinc is positive but limited, and use would generally be considered as a component of a broader nutritional strategy rather than adequate as a monotherapy. Nevertheless, the use of concomitant zinc at a low dosage level, 10 to 40 mg elemental zinc daily depending on weight and age, may be beneficial and is generally safe and unlikely to produce clinically significant adverse effects.

Health care professionals experienced in nutritional therapies typically emphasize reduced sugar intake and other blood glucose stabilization measures, removal of artificial additives (especially dyes) from diet, observation of intolerance to potentially reactive foods, and coadministration of nutrients, on a personalized basis, such as essential fatty acids (eicosapentaenoic acid [EPA], docosahexaenoic acid [DHA], gamma-linolenic acid [GLA], linoleic acid), oligomeric proanthocyanidins (e.g., pine bark, grape seed extract), magnesium, chromium, L-carnitine, and B vitamins.

Androgens

Fluoxymesterone (Halotestin); testosterone cypionate; methyltestosterone (Android, Methitest, Testred, Virilon).
Related but evidence lacking for extrapolation: Methyltestosterone combination drug: methyltestosterone and esterified estrogens (Estratest, Estratest HS); testolactone (Testolacton; HSDB 3255, SQ 9538; Fludestrin, Teolit, Teslac, Teslak).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
3. Possible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Various androgens are administered clinically for treatment of diverse conditions. Zinc plays a key role in normal male sexual development, prostate function, and the maturation of sperm, as well as ovulation and fertilization. Further, zinc deficiency can cause hypogonadism, with a possible contribution from impaired leptin secretion.[72] Zinc may raise serum testosterone and dihydrotestosterone levels and sperm counts in some men, particularly those with low sperm counts, possibly by stimulating testosterone production in Leydig cells.[73-75]

Coadministration of zinc during androgen treatment (e.g., infertile men with insufficient sperm motility) may enhance the efficacy of treatment, and in fact, zinc appears to be essential for such functions. The mechanisms of action involved in this synergistic interaction have not been fully elucidated.

Research

Limited evidence from clinical trials indicates that coadministration of zinc with androgens may enhance therapeutic outcomes, particularly in males with low baseline zinc levels. Castro-Magana et al.[76] investigated the role of zinc in boys with constitutional growth delay, familial short status, and delayed appearance of secondary sexual characteristics. They measured hair and serum zinc levels in boys with growth delay and short status initially and then again after administering methyltestosterone. They determined that "zinc levels in boys beyond stage 3 of genital development are significantly higher than in stage 1 and 2," and they observed "a linear relationship between zinc levels and serum testosterone concentration (up to 250 ng/dL)." Moreover, they found that "methyltestosterone administration raised the zinc concentration in serum and hair, especially in boys with constitutional growth delay." Thus, a synergistic relationship between zinc and testosterone function was suggested, in that "increased endogenous production or exogenous supply of testosterone [is] associated with increased zinc levels." These authors concluded that "the relative testosterone deficiency and hypogonadotropism seen in constitutional growth delay may result in decreased zinc levels, which in turn could cause a further delay in the appearance of secondary sexual characteristics and greater growth retardation."

Subsequently, Takihara et al.[77] compared the effects of 3 months of zinc therapy (zinc sulfate, 220 mg twice daily), low-dose androgen therapy (fluoxymesterone, 5-10 mg daily), and combination therapy (zinc sulfate and low-dose fluoxymesterone) on sperm motility and seminal zinc concentration in infertile patients with decreased motility and different zinc concentrations. They found that low-dose androgen therapy "increased seminal zinc concentrations and sperm motility, only when pretreatment seminal zinc concentrations were low. Furthermore, patients with low seminal zinc concentrations and poor sperm motility showed greater improvement of sperm motility and seminal zinc levels in response to zinc sulfate along with fluoxymesterone than they did to fluoxymesterone alone or zinc sulfate alone, possible due to a synergistic effect of zinc and androgen."

These consistent but preliminary findings suggest that further research through well-designed and adequately powered clinical trials is warranted, with a focus on determining safety parameters and significators of pretreatment zinc status.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating patients with androgen therapy are advised to assess zinc status and coadminister a highly bioavailable zinc salt preparation (e.g., 55 mg elemental zinc twice daily) when indicated. Judicious standards of practice suggest monitoring for adverse effects of excessive zinc and coadministration of copper (1-3 mg daily, depending on baseline plasma or serum zinc/copper ratio).

Antibiotics and Antimicrobial Agents (Systemic)

Aminoglycoside antibiotics: Amikacin (Amikin), gentamicin (G-mycin, Garamycin, Jenamicin), kanamycin (Kantrex), neomycin (Mycifradin, Myciguent, Neo-Fradin, NeoTab, Nivemycin), netilmicin (Netromycin), paromomycin (monomycin; Humatin), streptomycin, tobramycin (AKTob, Nebcin, TOBI, TOBI Solution, TobraDex, Tobrex).

Beta-lactam antibiotics: Methicillin (Staphcillin); aztreonam (Azactam injection); carbapenem antibiotics: meropenem (Merrem I.V.); combination drug: imipenem and cilastatin (Primaxin I.M., Primaxin I.V.); penicillin antibiotics: amoxicillin (Amoxicot, Amoxil, Moxilin, Trimox, Wymox); combination drug: amoxicillin and clavulanic acid (Augmentin, Augmentin XR, Clavulin); ampicillin (Amficot, Omnipen, Principen, Totacillin); combination drug: ampicillin and sulbactam (Unisyn); bacampicillin (Spectrobid), carbenicillin (Geocillin); cloxacillin (Cloxapen), dicloxacillin (Dynapen, Dycill), mezlocillin (Mezlin), nafcillin (Unipen), oxacillin (Bactocill), penicillin G (Bicillin C-R, Bicillin L-A, Pfizerpen, Truxcillin), penicillin V (Beepen-VK, Betapen-VK, Ledercillin VK, Pen-Vee K, Robicillin VK, Suspen, Truxcillin VK, V-Cillin K, Veetids), piperacillin (Pipracil); combination drug: piperacillin and tazobactam (Zosyn); ticarcillin (Ticar); combination drug: ticarcillin and clavulanate (Timentin).

Cephalosporin antibiotics: Cefaclor (Ceclor), cefadroxil (Duricef), cefamandole (Mandol), cefazolin (Ancef, Kefzol), cefdinir (Omnicef), cefepime (Maxipime), cefixime (Suprax), cefoperazone (Cefobid), cefotaxime (Claforan), cefotetan (Cefotan), cefoxitin (Mefoxin), cefpodoxime (Vantin), cefprozil (Cefzil), ceftazidime (Ceptaz, Fortaz, Tazicef, Tazidime), ceftibuten (Cedax), ceftizoxime (Cefizox), ceftriaxone (Rocephin), cefuroxime (Ceftin, Kefurox, Zinacef), cephalexin (Keflex, Keftab), cephapirin (Cefadyl), cephradine (Anspor, Velocef); imipenem combination drug: imipenem and cilastatin (Primaxin I.M., Primaxin I.V.); loracarbef (Lorabid), meropenem (Merrem I.V.).

Fluoroquinolone (4-quinolone) antibiotics: Cinoxacin (Cinobac, Pulvules), ciprofloxacin (Ciloxan, Cipro), enoxacin (Penetrex), gatifloxacin (Tequin), levofloxacin (Levaquin), lomefloxacin (Maxaquin), moxifloxacin (Avelox), nalidixic acid (Neggram), norfloxacin (Noroxin), ofloxacin (Floxin, Ocuflox), sparfloxacin (Zagam), trovafloxacin (alatrofloxacin; Trovan).

Macrolide antibiotics: Azithromycin (Zithromax), clarithromycin (Biaxin), dirithromycin (Dynabac), erythromycin oral (EES, EryPed, Ery-Tab, PCE Dispertab, Pediazole), troleandomycin (Tao).

Sulfonamide antibiotics: Sodium sulfacetamide (AK-Sulf, Bleph-10, Sodium Sulamyd), sulfamethoxazole (Gantanol), sulfanilamide (AVC), sulfasalazine (salazosulfapyridine, salicylazosulfapyridine, suphasalazine; Apo-Sulfasalazine, Azulfidine, Azulfidine EN-Tabs, PMS-Sulfasalazine, Salazopyrin, Salazopyrin EN-Tabs, SAS), sulfisoxazole (Gantrisin); combination drug: sulfamethoxazole and trimethoprim (cotrimoxazole, co-trimoxazole, SXT, TMP-SMX, TMP-sulfa; Bactrim, Bactrim DS, Cotrim, Septra, Septra DS, Sulfatrim, Uroplus); triple sulfa (Sultrin Triple Sulfa).

Miscellaneous antibiotics: Bacitracin (Caci-IM), chloramphenicol (Chloromycetin), chlorhexidine (Peridex), clindamycin, oral (Cleocin); colistimethate (Coly-Mycin M), dapsone (DDS, diaminodiphenylsulphone; Aczone Gel, Avlosulfon), furazolidone (Furoxone), lincomycin (Lincocin), linezolid (Zyvox), nitrofurantoin (Macrobid, Macrodantin), trimethoprim (Proloprim, Trimpex), vancomycin (Vancocin).

Effect and Mechanism of Action

Administration of zinc may prevent or, in conjunction with standard oral antibiotic therapy and vitamin A, may enhance the acute treatment and accelerate recovery of infants and children with pneumonia.[78,79] The role of zinc in immune function, generally by restoring immunocompetence and specifically as an acute-phase reactant, is presumed to provide the primary mechanism of action. However, such effect may occur only to the degree that nutrient coadministration corrects inadequate zinc intake or preexisting zinc deficiency.

During the "hot season," concomitant zinc may delay recovery of some children and infants being treated for pneumonia with standard oral antibiotics. The mechanism of such a potential adverse effect has not been elucidated.[57]

Research

The body of evidence on the effects of zinc in preventing and treating pneumonia, diarrhea, and other common diseases in malnourished infants and children is emerging and suggestive of a pattern of benefit but, as yet, mixed and incomplete. In a meta-analysis of randomized controlled trials, Bhutta et al.[78] found that zinc supplementation in children in developing countries is associated with substantial reductions in the rates of pneumonia and diarrhea. In a randomized controlled trial involving 2482 children age 6 months to 3 years in an urban slum, Bhandari et al.[80] found that zinc supplementation (with infants receiving 10 mg elemental zinc daily and older children 20 mg daily) "substantially reduced the incidence of pneumonia" in children who received single pharmacological dose of vitamin A (100,000 IU for infants and 200,000 IU for older children) at enrollment. In contrast, that same year (2002), in a double-blind, randomized controlled trial involving children age 9 months to 15 years in Calcutta, Mahalanabis et al.[81] found that children with severe measles accompanied by pneumonia did not demonstrate any additional benefit, beyond that provided by antibiotics and vitamin A palmitate (100,000 IU dose), from coadministration of zinc acetate (containing 20 mg elemental zinc) twice daily for 6 days.

Subsequently, in a double-blind, placebo-controlled clinical trial involving 270 children age 2 to 23 months in a Bangladesh hospital, Brooks et al.[79] compared the effects of concomitant elemental zinc (20 mg/day) versus placebo in combination with the hospital's standard antimicrobial management. Children in the zinc treatment group demonstrated reduced duration of severe pneumonia, including duration of chest indrawing, accelerated respiratory rate (>50 breaths/min), and hypoxia, and a shortened duration of overall hospitalization, with a mean reduction equivalent to one hospital day for both severe pneumonia and time in hospital. Less benefit was observed in children with wheezing. These researchers concluded that coadministration of "20 mg zinc per day accelerates recovery from severe pneumonia in children, and could help reduce antimicrobial resistance by decreasing multiple antibiotic exposures, and lessen complications and deaths where second line drugs are unavailable."[79] However, in a later, randomized,

double-blind, placebo-controlled clinical trial involving 299 children, also age 2 to 23 months, being treated for severe pneumonia with standard antibiotic therapy in a hospital in southern India, Bose et al.[57] reported a lack of therapeutic benefit from 10 mg zinc sulfate, versus placebo, twice a day during hospitalization. Specifically, they observed "no clinical or statistically significant differences in the duration of tachypnea, hypoxia, chest indrawing, inability to feed, lethargy, severe illness, or hospitalization." Moreover, they reported "significantly longer duration of pneumonia in the hot season" in subjects treated with concomitant zinc.

The conflicting findings from this study compared with previous trials indicate that the value of zinc in preventing or correcting zinc deficiency may be the pivotal variable in the therapeutic response. Furthermore, the unexpected possibility of adverse effects, as seen in the "hot season" subgroup analysis, suggests the inadequacy of data underlying recommendations for routine administration of zinc in the treatment of pneumonia in young children in the developing world and the need for continued research with an emphasis on zinc-deficient populations.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating infants and children with pneumonia, or other severe acute lower respiratory infection, are advised to consider coadministration of zinc, and possibly vitamin A, with standard antibiotic therapy in patients demonstrating or at high risk for compromised zinc status. A dose of 10 mg elemental zinc twice daily is typical but can vary depending on the child's age and weight. Current scientific knowledge suggests that such doses are unlikely to produce any adverse effects during a short course of treatment, but limited data suggest greater caution in hot climates. Methods for determining zinc deficiency are generally considered unreliable, so patient history and clinical presentation are usually the best predictors of zinc deficiency. Health care professionals are also advised to educate parents to shift dietary intake patterns away from foods with a high phytate-to-zinc ratio in order to increase the bioavailability of dietary zinc. In general, zinc acetate provides the most bioavailable form of zinc, across a broad range of gastric pH. The potential for a pharmacokinetic interaction involving binding between zinc and the antibiotic agent suggests that separating oral intake by 2 to 4 hours would be prudent.

Antibiotics, Topical

Erythromycin 3% and benzoyl peroxide 5% topical gel (Benzamycin).
Clindamycin, topical (Cleocin T, Clindaderm).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Effect and Mechanism of Action

The important role of zinc in immune function and the health of the skin is well established.[82] Zinc is effective in the treatment of inflammatory acne, and zinc salts have demonstrated bacteriostatic activity against *Propionibacterium acnes*.[83] Zinc appears to exert a specific action on inflammatory cells, especially granulocytes, where the mechanism involved in zinc's "anti-inflammatory action is related to inhibition of polymorphonuclear leukocyte chemotaxis induced by a decreased granulocyte zinc level."[84,85]

Concomitant administration of zinc, oral and/or topical solution, may enhance the efficacy of topical antibiotics in the treatment of acne vulgaris.

Research

A limited but consistent body of evidence indicates that erythromycin-zinc combination therapy is effective in the treatment of acne. In a double-blind, randomized, multicenter study involving 122 patients with acne vulgaris, Habbema et al.[86] evaluated the efficacy of a 4% erythromycin and zinc combination lotion (Zineryt) versus 2% erythromycin lotion (Eryderm). During visits at 0, 1, 2, 4, 8, and 12 weeks, they examined subjects and determined that treatment with erythromycin-zinc "combination lotion was more effective than with 2% erythromycin as regards the reduction in number of the acne lesions and the severity grade of the acne." Subsequently, Schachner et al.[87] conducted a 12-week double-blind trial to determine the safety and efficacy of a 4% erythromycin plus 1.2% zinc acetate formulation versus its vehicle. They continued the study for 40 weeks after the initial 12-week double-blind phase by switching vehicle-treated patients to active treatment and continuing to give patients treated with active drug the same treatment. Investigators reported "statistically significant differences" during the first 12 weeks "in the efficacy of the erythromycin-zinc compared with vehicle for acne severity grades (global assessment) and for papule, pustule, and comedo counts." Moreover, following crossover, the subjects who had been receiving vehicle-only (placebo) treatment and then had been switched to active therapy duplicated the improvement of the first group treated with erythromycin-zinc. The authors reported "no clinical problems with superinfection or secondary infection" during 1 year of treatment in the 39 female patients (of the initial 73).[87]

Dreno et al.[88] also conducted in vivo and in vitro studies investigating the combination of topical erythromycin and oral zinc gluconate in the treatment of patients with inflammatory acne. In a trial involving 30 patients with inflammatory acne, they found that treatment with zinc gluconate (30 mg daily for 2 months) resulted in "a reduction in the number of inflammatory lesions after a 2-month treatment whether or not *Propionibacterium acnes* carriage was present," as demonstrated in bacteriological samples taken at onset, day 30, and day 60. Further, they observed that in vitro "addition of zinc salts in the culture media of *Propionibacterium acnes* reduced resistance of *Propionibacterium acnes* strains to erythromycin." Thus, the authors concluded that the concomitant action of oral zinc salts acting systemically and topical erythromycin treatment "seems an interesting option in the light of an increasing number of patients carrying erythromycin resistant *Propionibacterium acnes* strains."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The scientific evidence, both broad and specific, indicates that health care professionals treating patients with acne, especially inflammatory acne, should consider integrating zinc into their therapeutic strategy. Whether by oral dose or combined in a topical preparation with an antibacterial agent, zinc can exert a beneficial effect directly and synergistically on the skin environment and broader immune function and on the pathological processes and pathogenic agents. A typical dose would be in the range of 20 to 40 mg elemental zinc per day orally and/or 1% to 2% topically. Continued zinc supplementation after cessation of antibiotics may be indicated in many patients as

part of a comprehensive and individualized long-term strategy emphasizing dietary changes, hormonal modulation, and other interventions appropriate to the patient's characteristics and evolving needs. Patients who have a history of multiple courses of oral antibiotics will often also benefit from coadministration of probiotic bacterial flora over an extended period, at least in part through effects on digestive and immune function.

Antidepressants, Including Tricyclic Antidepressants and Selective Serotonin Reuptake Inhibitor (SSRI) Antidepressants

Evidence: Amitriptyline (Elavil), citalopram (Celexa), clomipramine (Anafranil), fluoxetine (Prozac, Sarafem).
Extrapolated, based on similar properties:
Tricyclic antidepressants: Amitriptyline combination drug: amitriptyline and perphenazine (Etrafon, Triavil, Triptazine); amoxapine (Asendin), desipramine (Norpramin, Pertofrane), doxepin (Adapin, Sinequan), imipramine (Janimine, Tofranil), nortriptyline (Aventyl, Pamelor), protriptyline (Vivactil), trimipramine (Surmontil).
Selective serotonin reuptake inhibitor (SSRI) antidepressants: Escitalopram (S-citalopram; Lexapro), fluvoxamine (Faurin, Luvox), paroxetine (Atropax, Deroxat, Paxil, Seroxat), sertraline (Zoloft).

Effect and Mechanism of Action

Among its many functions, zinc is an important modulator of the CNS. In particular, hippocampal and cortical neurons, noted for high concentrations of zinc, "possess mechanisms for Zn^{2+} uptake and storage in synaptic terminals" and for stimulation of release of Zn^{2+} ions along with neurotransmitters. "Zn^{2+} modulates predominantly the excitatory (glutamatergic) and inhibitory (GABA-ergic) amino acid neurotransmission pathways in CNS."[66] Thus, zinc deficiency impairs neurological function and is associated with depression.[4,89-91]

Administration of zinc in patients diagnosed with depression may provide direct benefit and appears to enhance the effect of some conventional antidepressant medications, particularly those affecting monoamine transmitter reuptake or metabolism, at least in part by acting as a modulator of glutamatergic transmission.[4,92] Chronic zinc administration, as well as most "clinically effective antidepressants," induce expression of the gene coding for brain-derived neurotrophic factor (BDNF) and an increase in cortical (but not hippocampal) BDNF messenger RNA (mRNA) level; tranylcypromine, a classic antidepressant, increases BDNF mRNA level in both brain regions. Zinc administration also increases levels of synaptic pool zinc in the hippocampus.[2,4] Moreover, changes in the brain, particularly a phenomenon known as "mossy fiber sprouting," that occur with electroconvulsive shock (ECS), are associated with an increase in the synaptic zinc level in the hippocampus after such therapy and parallels effects of chronic but not acute zinc treatment.[3] "Chronic treatment with citalopram (but not with imipramine or ECS) significantly (approx 20%) increased the serum zinc level. Chronic treatment with both drugs slightly (by approx 10%) increased the zinc level in the hippocampus and slightly decreased it in the cortex, cerebellum and basal forebrain." Chronic imipramine treatment enhances the ability of zinc to inhibit the NMDA receptor complex in the cerebral cortex, but not in the hippocampus, but such effects appear to be species specific.[93] Notably, chronic ECS may also induce a significant increase in zinc levels in the hippocampus (30%), as well as an 11% to 15% increase in zinc in other brain regions.[94] Another mechanism of action may derive from zinc's "antagonistic action on group I metabotropic glutamate receptors or potentiation of AMPA receptors which both may attenuate the NMDA receptor function."[4,95,96] Zinc may also exert an antidepressant action through its direct inhibition of glycogen synthase kinase-3β, which has been proposed as a target for treatment of affective (bipolar) disorder.[97] Thus, zinc acts as a natural modulator of amino-acidergic neurotransmission, particularly as an antagonist of the glutamate/*N*-methyl-D-aspartate (NMDA) receptor, and zinc administration may correct derangements of zinc homeostasis so that its presence may be necessary for, and its coadministration may potentiate, the therapeutic effects of many conventional antidepressants.

Research

McLoughlin and Hodge[89] initially published data reporting hypozincemia in patients with primary depressive disorders. Subsequently, one study by Maes et al.[90] showed significantly lower serum zinc levels in individuals diagnosed with major depression, compared with nondepressed controls, and intermediate zinc levels in those with minor depression. In another study, however, these researchers found no correlation between these parameters among treatment-resistant patients.[98] Further correlations have been observed between the serum level of zinc and the severity of illness in individuals with unipolar depression, as defined in the Hamilton Depression Rating Scale. The hypothesis that zinc status, as indicated by serum zinc concentrations, may be a sensitive and specific marker of depression is also supported by findings showing that lowered serum zinc concentrations may be normalized after successful antidepressant treatment.[4,89,98-100]

In a series of in vitro and animal studies and human trials spanning nearly a decade, Polish researchers have investigated the function of zinc in relation to depression and the interactions between zinc and conventional antidepressants. They showed a similar "antidepressant-like performance" in mice and rats subjected to the forced-swim test, but also found differences in the effects of imipramine on locomotor function and in the responses of these two rodent species to chronic imipramine treatment that suggest the existence of species-dependent adaptive mechanisms involving zinc sites at the NMDA receptor complex.[93,101,102] Further, a rodent model showed that the addition of low-dose zinc could potentiate the activity of antidepressants when administered at dosages too low to be effective and could synergistically achieve an antidepressant effect.[101,103] In one innovative study, Nowak et al.[104] demonstrated that the alteration in zinc interaction with NMDA receptors may be involved in psychopathology underlying suicidal attempts by showing a statistically significant (26%) reduction in the potency of zinc to inhibit NMDA receptor activity in the hippocampal, but not cortical, tissue of suicide subjects. Subsequently, these researchers conducted a placebo-controlled, double-blind pilot study investigating the efficacy of concomitant zinc (25 mg Zn^{2+}) and standard antidepressant pharmacotherapy using tricyclic antidepressants or SSRIs, specifically clomipramine, amitriptyline, citalopram, or fluoxetine, in the treatment of fourteen patients who fulfilled *Diagnostic and Statistical Manual of Mental Disorders* (4th edition, *DSM-IV*) criteria for major (unipolar) depression. Initially, after an initial washout period and throughout

12 weeks of treatment with antidepressant drugs and zinc or antidepressant drugs and placebo, they assessed therapeutic response to intervention using the Hamilton Depression Rating Scale and the Beck Depression Inventory. Subjects in both groups demonstrated an improvement in depressive symptoms at the second week, but the zinc-antidepressant group showed a statistically significant improvement in both measures, compared with the antidepressant-placebo group, at 6 and 12 weeks. The authors concluded that their findings, although preliminary, constituted "the first demonstration of the benefit of zinc supplementation in antidepressant therapy" and suggested that the effect "may be related to modulation of glutamatergic or immune systems by zinc ion."[92] Continued investigation of this interaction and its clinical implications is clearly warranted.

Greater refinement in methodology, to account for individual patient characteristics (e.g., clinical variation in condition, pharmacogenomics, personal history, lifestyle characteristics), will render future findings more robust and relevant to the dynamic and nuanced realities of treating the diverse presentations of depression. More broadly, further research, possibly framed within the more expansive model of psychoneuroimmunology, is warranted to investigate the potentially pivotal role of zinc in the interrelationships between the "immune system" and CNS function and thereby reveal the overarching unity of these supposedly discrete "systems" within human physiology and health, dysfunction and disease.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Health care professionals treating individuals diagnosed with depression, particularly physicians prescribing SSRI or tricyclic antidepressants, are advised to consider the potential value of zinc administration as part of a comprehensive, evolving, and individualized therapeutic strategy. The emerging body of scientific evidence strongly suggests that zinc may independently benefit many such patients, even outside compromised zinc status, and may enhance the efficacy of conventional antidepressant regimens, including pharmaceutical antidepressants and possibly electroconvulsive therapy. Pending further research, and the establishment of sensitive assays of zinc depletion, physiologic zinc administration, typically 25 to 40 mg elemental zinc daily, is generally considered safe and sufficient to achieve therapeutic effect. Coadministration of folic acid, DHEA, EPA (fish oil), inositol, or other synergistic nutritional support may also be efficacious with certain patients. Concomitant use of botanical medications, such as *Hypericum perforatum* (St. John's wort), *Ginkgo biloba*, *Rhodiola rosea*, *Withania somnifera* (Ashwaganda), is controversial and may be useful but requires assessment, prescribing, and management by a health care professional trained and experienced in botanical therapeutics, in coordination with the physician prescribing any pharmacotherapy.

Effect and Mechanism of Action

The ACE inhibitors possess a prominent zinc-binding moiety that binds to zinc ions in the active site of the ACE molecule. Drugs within the class of ACE inhibitors can be classified according to the ligand of the zinc ion of ACE and according to the excretion route of their active moiety. Thus, captopril has a sulfhydryl moiety as the zinc-binding ligand, whereas enalapril has a carboxyalkyl dipeptide moiety. Both captopril and enalapril are excreted primarily through the kidneys, but enalapril has a much longer duration of action than captopril. Gradual zinc depletion occurs as zinc is bound to the ACE inhibitor and can lead to zinc insufficiency. Some of the adverse effects associated with ACE inhibitors, such as hypogeusia, coincide with known characteristics of zinc depletion and may derive, at least in part, from the effect of these agents on zinc status.

Research

Several studies have demonstrated that captopril (and, at a slower pace, enalapril) is likely to cause significant urinary zinc loss, which over several months can lead to zinc depletion with attendant decreased red blood cell (RBC) zinc concentrations and reduced taste acuity (hypogeusia), even in the absence of adverse changes in serum zinc levels. In 1987, O'Connor et al.[105] reported that serum zinc was unaffected by captopril treatment of hypertension. However, the next year, Abu-Hamdan et al.[106] documented changes in taste acuity and zinc metabolism in a trial involving 31 hypertensive male patients treated with captopril. In comparing 11 long-term, high-dose captopril recipients (>6 months, 266 mg/day), six short-term captopril recipients (<6 months, 104 mg/day), and 14 noncaptopril controls, they found that, compared to controls, the long-term captopril group had significantly higher taste detection and recognition thresholds, lower plasma zinc, and higher urinary zinc excretion. The short-term captopril group did not differ significantly from the noncaptopril group, except for altered taste-recognition thresholds. Notably, two long-term captopril patients reported improved taste acuity and demonstrated "almost normalized zinc parameters" after discontinuing captopril.

Subsequently, Golik et al.[107] conducted two trials comparing the effects of captopril and enalapril on zinc metabolism in hypertensive patients. First, in a small retrospective study, they assessed several parameters of zinc metabolism in 13 patients with essential hypertension, of whom six were chronically taking captopril, seven were taking enalapril, and six were untreated, as well as nine healthy controls. Although serum zinc levels were comparable in all groups, the captopril-treated subjects exhibited significantly increased 24-hour urinary zinc excretion compared with the three other groups.

Further, subjects in both the captopril and the enalapril group exhibited a significant increase in the zinc/creatinine ratio in 24-hour urine, which was significantly greater in the captopril group. Notably, even though plasma zinc concentrations were comparable in all groups, subjects in the captopril group demonstrated significantly decreased RBC zinc values compared with those in the three other groups. The authors concluded that "(1) although both captopril and enalapril produce renal zinc loss, this loss is far greater in patients receiving captopril; and (2) captopril administration over 3 months or more generates RBC zinc depletion."[107] Several years later, in a prospective trial involving 44 subjects, these researchers investigated the effects of chronic captopril and enalapril treatment on zinc metabolism in hypertensive patients. They measured and compared zinc levels in serum, 24-hour urine samples, and peripheral blood monocytes at baseline and after 6 months in 10 patients newly diagnosed with essential hypertension who were randomly divided for ACE therapy, with 16 receiving captopril only and 18 receiving enalapril only, as well as 10 healthy subjects serving as controls. They found that patients in the captopril- and enalapril-treated groups demonstrated significantly decreased intramonocytic zinc levels over the same period, but that only subjects in the captopril-treated group showed a significant enhancement of 24-hour urinary zinc excretion after 6 months of treatment. Thus, the authors concluded: "Treatment of hypertensive patients with captopril or enalapril may result in zinc deficiency."[108]

Subsequently, Peczkowska[109] confirmed that ACE inhibitor therapy may adversely affect zinc metabolism. Although not statistically significant, serum zinc decreased more significantly in a group treated with captopril after 8 weeks of therapy than in a group receiving benazepril. Collectively, these findings indicate that captopril can cause clinically significant zinc depletion over several months, which may not be detectable through serum zinc assay. Other ACE inhibitors probably have a similar effect on zinc metabolism, although zinc depletion at the tissue level apparently occurs at a slower rate and possibly to a lesser degree.

In related research, Golik et al.[110] also determined that individuals with type 2 diabetes mellitus and congestive heart failure "excrete larger amounts of zinc, which may eventually lead to zinc deficiency." These findings bear directly on the data relating to hypertensive medications, given the widespread use of ACE inhibitors for heart failure and the high incidence of hypertension among these patient populations.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing captopril or other ACE inhibitors are advised to discuss supportive coadministration of zinc (50 mg elemental zinc twice daily) to counter probable nutrient depletion. The risk attendant to such supplementation is minimal and its characteristics well known. Establishing zinc depletion through laboratory assessment is not considered sensitive enough to be clinically reliable because of the limitations of testing methods in the face of metabolic flux characteristic of zinc physiology. Clinical signs of zinc deficiency are more reliable but tend to manifest only with advanced deficiency, usually after subclinical depletion has adversely affected function. Patients who develop ACE inhibitor–associated cough, frequently cited as a cause of nonadherence, may also experience amelioration with iron supplementation.[111] Concomitant synergistic minerals (e.g., magnesium) as well coenzyme Q10 and hawthorn *(Crataegus)* could potentially further enhance therapeutic outcomes in the treatment of hypertension, heart failure, and related cardiovascular disease. Copper is generally advisable to balance the potential depletion by zinc. However, to avoid absorption problems inhibiting bioavailability of both ACE inhibitors and zinc (as well as other nutrients), patients should wait at least 2 hours after administration of the medication before taking any supplements.

Supplementation of any minerals by patients with renal failure or on dialysis can be dangerous and should only be done within the context of close medical supervision. Patients receiving ACE inhibitor therapy may experience an exaggeration of adverse effects often associated with intravenous administration of iron salts; monitor closely for adverse effects such as nausea, vomiting, and hypotension. Notably, potassium is usually contraindicated with ACE inhibitors because they greatly decrease renal potassium excretion.

Chlorhexidine

Chlorhexidine (Chlorobex, Corsodyl, Eludril, Oro-Clense, Peridex, Periogard Oral Rinse).
Similar properties but evidence indicating no or reduced interaction effects: Periochip.

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:	Evidence Base:
2. Probable	○ **Preliminary**

Effect and Mechanism of Action

Chlorhexidine is known to cause staining of teeth when used as a rinse in dental care. The combination of zinc or other metal ions in solution with chlorhexidine can reduce the severity of such staining and enhance the plaque-inhibiting effect of the treatment. Zinc and other metal ions, such as tin (usually in the form of stannous fluoride), have the same receptor sites as chlorhexidine in the oral cavity, such that binding affinity for chlorhexidine is greater when the ions were applied together.

Research

The research into this interaction is preliminary in nature and limited in scope but consistent in its findings and their rationale. Waler and Rolla[112] investigated the plaque-inhibiting effect of chlorhexidine in combination with zinc (and tin) in a group of students. They observed that "chlorhexidine and zinc (0.2% and 0.3% respectively) gave a plaque inhibiting effect slightly better than chlorhexidine alone" and superior to pre-rinses with metal ions or chlorhexidine first and metal ions afterward. They concluded that "the metal ions and chlorhexidine have the same receptor sites in the oral cavity, chlorhexidine exhibiting the stronger affinity when the ions were applied together."

Subsequently, in a 6-month, randomized, stratified double-blind parallel study with 208 participants, Sanz et al.[113] investigated the effect of a dentifrice containing chlorhexidine and zinc on plaque, gingivitis, calculus, and tooth staining. Of the three test groups, the two receiving chlorhexidine as part of their treatment (with or without zinc) exhibited "significant reductions in plaque and gingivitis (gingival index and number of bleeding sites)... compared with the control group," but tooth staining was also higher. The group treated with the chlorhexidine-zinc rinse exhibited "significantly less staining compared with the positive control." These authors concluded that the chlorhexidine-zinc dentifrice "will contribute to a significant improvement in oral hygiene with less staining

compared with using a 0.12% chlorhexidine rinse." Further clinical trials are warranted given the positive findings of these preliminary studies. The stability and acidic nature of these formulations in clinical practice are among the potential concerns deserving attention.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Dental professionals administering chlorhexidine are advised to consider adding zinc, usually as zinc sulfate heptahydrate, to their chlorhexidine preparation. No significant adverse effects, other than the probable bad taste, are to be expected. Direct evidence is lacking to confirm the efficacy of oral zinc administration alone in achieving similar preventive effects. Perhaps more importantly, clinicians should educate patients that brushing before applying the dentifrice is the most effective way to reduce chlorhexidine staining, because chlorhexidine adheres to plaque. Likewise, cultivating a healthy oral environment, by reducing acidity and supporting healthy oral flora, is also essential to preventing caries and erosion.

Ciprofloxacin and Related Fluoroquinolone (4-Quinolone) Antibiotics

Evidence: Ciprofloxacin (Ciloxan, Cipro), norfloxacin (Noroxin); 8-hydroxyquinoline.

Effect and Mechanism of Action

Zinc salts and the 3-carbonyl and 4-oxo functional groups on quinolone antibiotics can bind within the gastrointestinal (GI) tract to form a poorly absorbed, stable chelation complex. This binding process, which may not be limited to the gut, can interfere to varying degrees with the absorption, bioavailability, and activity of both the antimicrobials in this class and the orally administered preparations containing zinc.[114-120]

In one permutation of this interaction with a related quinolone, coadministration of zinc oxide may form chelates that inhibit the antibacterial activity or even counteract the antimycotic activity of 8-hydroxyquinoline, but may also mitigate allergic reactions to the 8-hydroxyquinoline.[121]

Research and Reports

In vitro experiments first demonstrated the pattern of interaction between quinolones and metals in an aqueous medium and the resultant effects on antimicrobial activity. Subsequently, changes in oral bioavailability and alterations in therapeutic efficacy have been the focus of many previous interaction studies involving metal cations and quinolones. Thus, through multiple lines of research, the ability of multivalent cations to reduce the absorption and serum levels of oral quinolone antibiotics is generally considered well established.

Evidence from clinical trials focusing on zinc-quinolone interactions is limited. Most of the evidence used to predict direct, one-to-one interactions between zinc and various quinolone agents is extrapolated from findings based on research involving iron and based on similar chemistry and presumed mechanisms of action. Similarly, calcium, magnesium, manganese, and copper, as well as milk and calcium-fortified juices, inhibit absorption of fluoroquinolones. Much of the remaining data derive from studies using multimineral preparations, usually with iron the primary interacting agent. The situation with case reports is similar. In a four-way crossover trial with 12 healthy volunteers, Polk et al.[114] (1989) observed a clinically significant reduction in the absorption of orally administered doses of ciprofloxacin (500 mg) when administered with a multivitamin-mineral formulation containing zinc, or ferrous sulfate (325 mg orally three times daily). Notably, peak concentrations of ciprofloxacin with ferrous sulfate regimen were below the minimum inhibitory concentration (MIC) for 90% of strains of many organisms normally considered susceptible to the antimicrobial activity of ciprofloxacin. Kara et al.[116] investigated clinical and chemical interactions between ciprofloxacin and iron preparations and found impairment of absorption with a multimineral preparation containing iron, magnesium, zinc, calcium, copper, and manganese (Centrum Forte). In an experiment involving eight healthy volunteers, each receiving a different metal ion, Campbell et al.[117] found that zinc sulfate reduced the urinary recovery of norfloxacin by 56%, just slightly more than ferrous sulfate. In reviewing the available data, Stockley[122] concluded: "There seems to be very little data about the zinc/quinolone interaction, but zinc appears to interact like iron so that the same precautions suggested for iron should be followed."

The particular interaction between zinc oxide and 8-hydroxyquinoline, a related quinoline, is more nuanced, although the data are rather limited. In a case report and subsequent trial involving 13 patients, Fischer[121] found that zinc oxide in a base reduced the eczematogenic effects associated with 8-hydroxyquinoline compared with an ointment using a paraffin base without zinc. However, this combination also inhibited the antibacterial and antimycotic activity of the medication and appeared to promote the growth of *Candida albicans*. Consequently, this interaction, particularly chelate formation, can interfere with the therapeutic effects of the 8-hydroxyquinoline to the degree that substantially "little or no antibacterial properties" remain.[122,123]

Zinc depletion resulting from chelation by this class of medications has not been studied per se. Although plausible, such an adverse effect on zinc status is highly improbable given the limited duration of standard fluoroquinolone antibiotic use. Long-term quinolone therapy and simultaneous oral zinc intake in the face of zinc deficiency could theoretically contribute to lack of tissue repletion. It is unclear whether long-term

oral fluoroquinolone antibiotic therapy might cause clinically significant zinc depletion in certain vulnerable populations by preventing dietary zinc absorption.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The reduction of fluoroquinolone activity by simultaneously ingested zinc salts is a widely accepted, although not necessarily well-documented, interaction between these two groups of agents; the potential depletion of zinc through the same mechanisms is plausible but generally improbable in standard clinical use. Both directions of interaction and decreased bioavailability can be adequately avoided through proper patient education and dose timing. Notably, even with iron, the degree of interaction effect depends greatly on the particular quinolone agent involved, as well as timing of oral intake(s). Inherently, such separation of intake is irrelevant with combined topical formulations, and evidence indicates that the effectiveness of topical quinolone preparations may be compromised by the addition of zinc.

Patients with acute infections, diagnosed or presumed, frequently self-administer zinc because of its immune-supporting activity and often fail to inform their health care professionals. Physicians treating patients for serious infections with quinolone antibiotics should advise that they refrain from ingesting zinc supplements, or using multivitamin-mineral formulations containing zinc or other divalent mineral cations, during the course of therapy to avoid interfering with the absorption and thus the antimicrobial action of the medication.

Zinc intake can usually be temporarily halted in most patients but can be continued with separation of intake timing in those for whom concomitant zinc supplementation has been confirmed as necessary to other therapeutic needs. If this is not possible, administration of the medication 2 hours before or 6 hours after ingestion of an oral zinc or multimineral supplement is suggested and can effectively minimize risk of an adverse interaction (i.e., antibiotic malabsorption). This recommendation may also apply to intake of zinc-rich or zinc-fortified foods. Monitor for decreased therapeutic effects of oral quinolones if inadvertently administered simultaneously with oral zinc or multimineral supplements.

Clobetasol and Related Topical Corticosteroids

Evidence: Clobetasol (clobetasol topical; Cormax, Dermoval, Dermotyl, Dermovate, Dermoxin, Eumosone, Lobate, Olux, Temovate, Temovate E, Topifort).

Related, no evidence for extrapolation: Alclometasone (Aclovate, Modrasone), amcinonide (Cyclocort), beclomethasone, betamethasone dipropionate/valerate (betamethasone topical; Alphatrex, Beta-Val, Betaderm, Betanate, Betatrex, Diprolene AF, Diprolene, Diprosone, Luxiq, Maxivate, Teladar, Uticort, Valisone), clobetasone (Eumovate), clocortolone (clocortolone pivalate topical; Cloderm), desonide (DesOwen, Tridesilon), desoximetasone (Topicort, Topicort LP), desoxymethasone, dexamethasone (Aeroseb-Dex, Decaderm, Decadron, Decaspray), diflorasone (Apexicon, Florone, Maxiflor, Psorcon), diflucortolone (Nerisona, Nerisone), fluocinolone (Derma-Smoothe/FS, Fluonid, Synelar, Synemol), fluocinonide (Fluonex, Lidex, Lidex-E, Lonide, Vanos), fludroxycortide (flurandrenolone), fluocortolone (Ultralan), flurandrenolide (Cordran, Drenison), fluticasone (Cutivate), halcinonide (Halog), halobetasol (Ultravate); hydrocortisone 17-butyrate/acetate/probutate/valerate (hydrocortisone topical; Acticort100, Aeroseb-HC, Ala-Cort, Ala-Scalp HP, Allercort, Alphaderm, Bactine, Beta-HC, Caldecort Anti-Itch, Cetacort, Cort-Dome, Cortaid, Cortef, Cortifair, Cortizone, Cortone, Cortril, Delacort, Dermacort, Dermarest, DriCort, DermiCort, Dermtex HC, Epifoam, Gly-Cort, Hi-Cor, Hydro-Tex, Hytone, LactiCare-HC, Lanacort, Lemoderm, Locoid, MyCort, Nutracort, Pandel, Penecort, Pentacort, Proctocort, Rederm, S-T Cort, Synacort, Texacort, Westcort); mometasone (Elocon, mometasone topical), triamcinolone (Aristocort, Triderm, Kenalog, Flutex, Kenonel, triamcinolone topical); triamcinolone and nystatin (Mycolog II).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
3. Possible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Clobetasol is a synthetic glucocorticoid derived from cortisol. Possessing significant corticosteroid activity and minor mineralocorticoid activity, it is used clinically for its activity as a topical anti-inflammatory and immunosuppressant, particularly for corticosteroid-responsive dermatoses, and systemically in replacement therapy for adrenal insufficiency. Zinc has demonstrated beneficial effects in supporting healthy skin and immune function generally, and facilitating tissue repair in particular, as does biotin, with which it can be combined. Coadministration of zinc and topical clobetasol, along with other synergistic nutrients such as biotin, may provide for enhanced therapeutic effect in the treatment of inflammatory dermatological conditions.

Research

Limited research suggests a potential synergistic effect may be obtained from combining zinc and clobetasol, especially as part of a more comprehensive therapeutic strategy. In a published letter, Camacho and Garcia-Hernandez[123a] reported that children with alopecia areata exhibited greater improvement when administered a treatment combining topical clobetasol with zinc aspartate (100 mg daily) and biotin (20 mg daily) than did children treated with oral corticosteroids. These findings are promising but primarily serve to indicate that further research is warranted.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating inflammatory dermatological conditions such as alopecia areata with clobetasol or related topical corticosteroids may find that the addition of zinc, especially with other synergistic nutrients such as biotin, may enhance the therapeutic efficacy of the intervention. Patients should be advised of the preliminary nature of the scientific evidence, but also of the underlying rationale of the combination and the relatively low additional risk. In particular, such an approach may provide greater benefit and lesser adverse effects than oral corticosteroids.

Cisplatin

Cisplatin (*cis*-Diaminedichloroplatinum, CDDP; Platinol, Platinol-AQ).

See EDTA in Theoretical, Speculative, and Preliminary Interactions Research.

Corticosteroids, Oral, Including Prednisone

Betamethasone (Celestone), cortisone (Cortone), dexamethasone (Decadron), fludrocortisone (Florinef), hydrocortisone (Cortef), methylprednisolone (Medrol) prednisolone (Delta-Cortef, Orapred, Pediapred, Prelone), prednisone

(Deltasone, Liquid Pred, Meticorten, Orasone), triamcinolone (Aristocort).

Effect and Mechanism of Action

Zinc modulates acute immune response and promotes normal tissue repair. The adenohypophyseal-adrenocortical network plays a critical role in maintaining circulating zinc and in mobilizing zinc stores from tissue stores.[124] Under adrenocorticotropic hormone (ACTH) stress, the reaction of cortisol release is physiological, whereas the serum zinc level decreases significantly.[125] Thus, zinc metabolism can be significantly affected by both internal processes such as inflammation and exogenous influences such as glucocorticoid administration.

Oral corticosteroid medications, particularly at high doses, can cause increased urinary excretion of zinc and reduced serum zinc levels; significant effect is less probable with short-term, low-level corticosteroid administration.[124,126] Effects also vary through the course of steroid administration.

Zinc has been said to impair or interfere with the activity of corticosteroids or other immunosuppressant drug regimens because of its "immunostimulant" activity. No specific mechanism of action or other scientific data have been provided to support such assertions. This oversimplification likely derives from a misunderstanding of zinc's role in the immune system. Zinc deficiency is a documented cause of immune dysfunction, and zinc repletion restores normal immune function; however, zinc has not been demonstrated to act as an immune "stimulant."

Research

The scientific data on the interaction between corticosteroids and zinc have evolved over 30 years but still provide an incomplete understanding of the mechanisms involved and their clinical implications, especially with regard to the stages of immune response, tissue repair, and the role of the pituitary/adrenal axis in zinc metabolism. In 1971, Briggs et al.[126] reported that short-term, low-level prednisolone (5 or 10 mg/day) did not significantly effect serum zinc concentrations. That same year, Flynn et al.[124] published their findings on the effects on zinc during use of corticosteroids as vasodilators in the treatment of low-cardiac-output syndrome (LCOS) in patients with major burns (with or without LCOS) and surgical patients (with LCOS) compared with 30 elective or emergency surgery patients acting as controls. They noted that earlier researchers had found that elevated "serum and urine corticosteroids and, eventually, adrenocortical exhaustion have been reported in the early stages in severe burns," and that serum zinc "is also raised during the first day after the burn and starts to decrease rapidly after the seventh day."[127,128] Intravenous (IV) corticosteroids were administered in pharmacological doses to the major burn patients with LCOS (hydrocortisone, 800 mg every 6 hours) and in a vascular-surgery patient with LCOS (dexamethasone phosphate, 200 mg, equivalent to 8.0 g cortisone). They observed that "massive doses of steroids rapidly lower serum-zinc levels" in seriously ill burn patients and differentiated that response from the response to low-dose steroids as reported by Briggs. "The extent of pituitary/adrenal shutdown is likely to play a vital role in the differences between high and low dose effects." Both controls who underwent surgery and "major burn and L.C.O.S. patients receiving nonsteroid therapy had similar zinc patterns (i.e., increased zinc with the stress during the first days after injury or onset of L.C.O.S.)." However, only patients who received large doses of steroids exhibited rapid zinc loss. "Falls of 30-75 mcg per 100 ml were recorded as little as 1 hour after a single bolus of corticosteroids." Based on these and other findings, the authors concluded that the "actions of large doses of corticosteroids in major burn and L.C.O.S. patients point to a role for the adenohypophyseal/adrenocortical system in maintaining circulating zinc levels.... Increases and decreases in serum-zinc are linked to stress-induced activation and steroid-produced deactivation of the pituitary/adrenal axis" and as such indicate a central role of the pituitary/adrenal axis in regulating serum zinc changes and mobilizing body zinc stores.[124] Subsequent research by Fodor et al.[125] confirmed "that the zinc metabolism probably depends on glucocorticoidal controls."

Likewise, Yunice et al.[129] conducted an experiment comparing the effects of varying doses of a short-acting (methylprednisolone) and a long-acting (dexamethasone) synthetic glucocorticoid on extent and duration of alterations in plasma zinc and copper concentrations in normal humans. They observed increases in plasma zinc (and copper) levels shortly after IV administration of either steroid. However, plasma zinc concentrations decreased below control levels by 12 hours, and no significant decrease was noted beyond 48 hours; "the extent and duration of the depression depended on the dosage of the steroid administered." The authors concluded that their findings suggested "serum zinc levels may depend on ACTH-adrenal interactions."

In related research, Fell et al.[130] tracked zinc mobilization in two patients after hip replacement surgery and correlated it with muscle catabolism. They measured large increases in the daily excretion of zinc-65 (^{65}Zn), total zinc, and nitrogen, with the maximum excretion occurring about 10 days after surgery and observed a "good correlation between the increased excretion of ^{65}Zn and total zinc, indicating the tissue origin of the latter as skeletal muscle." Because ^{65}Zn is a radioactive form used only in research, these findings offer data more toward developing physiological knowledge than directly applicable to clinical monitoring of normal ^{64}Zn.

More broadly, research investigating the connections between endogenous steroid regulation and zinc metabolism might reveal valuable insights into the possible role of zinc status in the adverse effects of elevated cortisol, steroid release, and other components of stress response physiology that adversely affect immune function.

No evidence from clinical trials or qualified case reports substantiates broad assertions that zinc should not be administered concomitantly with corticosteroids or other immunosuppressant drug regimens because of its "immunostimulant" activity. Further research would be warranted should

preliminary findings strongly indicate the occurrence of such a phenomenon.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing oral corticosteroids are advised to consider the potential benefit of coadministering zinc as a therapeutic synergist and, in patients taking long-term steroids, for prevention of depletion. The available evidence indicates that zinc plays an important role in physiological response to trauma and participates in immune and tissue repair functions, as in cases involving severe burns. Moreover, both acute and chronic use of steroids can contribute to zinc depletion patterns. In some cases, depletion is more probable with administration for longer than 2 weeks. In other situations, however, acute depletion, especially in the context of injuries or pathologies putting high demands on physiological zinc metabolism, acute high-dose steroids may cause zinc depletion with greater potential for clinically significant adverse effects.

A daily dose of 15 to 50 mg elemental zinc per day, within the context of appropriate supervision, will generally facilitate healing and prevent depletion without introducing substantial risk of significant adverse effects. Although serum zinc was used for assessment in some relevant research, expert consensus agrees that no sensitive laboratory method exists for detecting zinc depletion in tissue stores and zinc pools. The theoretical concern that zinc might counteract intentional immunosuppressant activity lacks substantive evidence-based support and, even if true, might be beneficial in some cases and only potentially detrimental in others, depending on the condition being treated, patient characteristics, therapeutic strategy, and phase of treatment intervention. Further research through well-designed and adequately powered trials is warranted to determine safety and efficacy, mechanisms, indications, and treatment guidelines.

ESTROGENS, PROGESTINS, AND ESTROGEN-PROGESTIN COMBINATIONS

Oral Contraceptives: Monophasic, Biphasic, and Triphasic Estrogen Preparations (Synthetic Estrogen and Progesterone Analogs)

Ethinyl estradiol and desogestrel (Desogen, Ortho TriCyclen).
Ethinyl estradiol and ethynodiol (Demulen 1/35, Demulen 1/50, Nelulen 1/25, Nelulen 1/50, Zovia).
Ethinyl estradiol and levonorgestrel (Alesse, Levlen, Levlite, Levora 0.15/30, Nordette, Tri-Levlen, Triphasil, Trivora).
Ethinyl estradiol and norethindrone/norethisterone (Brevicon, Estrostep, Genora 1/35, GenCept 1/35, Jenest-28, Loestrin 1.5/30, Loestrin1/20, Modicon, Necon 1/25, Necon 10/11, Necon 0.5/30, Necon 1/50, Nelova 1/35, Nelova 10/11, Norinyl 1/35, Norlestin 1/50, Ortho Novum 1/35, Ortho Novum 10/11, Ortho Novum 7/7/7, Ovcon-35, Ovcon-50, Tri-Norinyl, Trinovum).
Ethinyl estradiol and norgestrel (Lo/Ovral, Ovral).
Etonogestrel/ethinyl estradiol vaginal ring (Nuvaring).
Mestranol and norethindrone (Genora 1/50, Nelova 1/50, Norethin 1/50, Ortho-Novum 1/50).
Related, internal application: Etonogestrel/ethinyl estradiol vaginal ring (Nuvaring).

Hormone Replacement Therapy (HRT), Estrogens

Chlorotrianisene (Tace); conjugated equine estrogens (Premarin); conjugated synthetic estrogens (Cenestin); dienestrol (Ortho Dienestrol); esterified estrogens (Estratab, Menest, Neo-Estrone); estradiol, topical/transdermal/ring (Alora Transdermal, Climara Transdermal, Estrace, Estradot, Estring FemPatch, Vivelle-Dot, Vivelle Transdermal); estradiol cypionate (Dep-Gynogen, Depo-Estradiol, Depogen, Dura-Estrin, Estra-D, Estro-Cyp, Estroject-LA, Estronol-LA); estradiol hemihydrate (Estreva, Vagifem); estradiol valerate (Delestrogen, Estra-L 40, Gynogen L.A. 20, Progynova, Valergen 20); estrone (Aquest, Estragyn 5, Estro-A, Estrone '5', Kestrone-5); estropipate (Ogen, Ortho-Est); ethinyl estradiol (Estinyl, Gynodiol, Lynoral).
Medroxyprogesterone-containing HRT and contraceptives: Medroxyprogesterone, oral (Cycrin, Provera); conjugated equine estrogens and medroxyprogesterone (Premelle cycle 5, Prempro).

Progestin/Progestogen-Only Oral Contraceptives, Implants, and Postcoital Contraceptives

Related, evidence lacking for extrapolation: Etonogestrel, implant (Implanon); levonorgestrel, implant (Jadelle, Norplant; Norplant-2); levonorgestrel, oral postcoital contraceptive (Duofem, Escapelle, Levonelle, Levonelle-2, Microlut, Microval, Norgeston, NorLevo, Plan B, Postinor-2, Vika, Vikela); medroxyprogesterone, injection (depot medroxyprogesterone acetate, DMPA; Depo-Provera, Depo-subQ Provera 104); NES progestin, implant (ST-1435, Nestorone); norgestrel, oral (Ovrette).

Hormone Replacement Therapy

Related, evidence lacking for extrapolation:
Estrogen/progestin combinations: Conjugated equine estrogens and norgestrel (Prempak-C); estradiol and dydrogesterone (Femoston); estradiol and norethindrone, patch (CombiPatch); estradiol and norethindrone/norethisterone, oral (Activella, Climagest, Climesse, FemHRT, Trisequens); estradiol valerate and cyproterone acetate (Climens); estradiol valerate and norgestrel (Progyluton); estradiol and norgestimate (Ortho-Prefest).
Estrogen/testosterone combinations: Esterified estrogens and methyltestosterone (Estratest, Estratest HS).

Interaction Type and Significance

≈≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, Not Requiring Professional Management**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable or
4. Plausible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

The use of oral contraceptives (OCs) may be associated with decreased serum levels of zinc.[131] Conversely, conjugated estrogens and medroxyprogesterone may reduce previously elevated urinary zinc excretion (as well as magnesium) in osteoporotic postmenopausal women.[132] No specific mechanisms have been established to explain the various observed interactions phenomena, singly or collectively.

Research

The effects of exogenous estrogens on zinc levels can vary depending on the form and dose of estrogen administered, concomitant agents in formulation, patient characteristics (including life stage), and therapeutic intent. A significant incidence of zinc deficiency has been documented in females of all

ages in a broad range of socioeconomic conditions, with the greatest risk in premature infants; low-income urban infants, children, adolescents, and women of childbearing age; and populations with a high-cereal diet.[8]

Dorea et al.[131] assessed serum levels of zinc and copper in 44 women of the same age group, 24 of whom were taking OCs and 20 serving as controls. They observed that "serum zinc was significantly lower while serum copper was significantly higher for women taking the oral contraceptive agents," but that there was "no significant correlation between the serum zinc and copper levels" in either group. In general, adolescents in the United States tend to have inadequate intake of zinc and other micronutrients, with dietary intakes of zinc less than 75% of the U.S. RDA in more than one-third and less than 50% using nutritional supplements.[9]

In a trial involving 37 postmenopausal women, some of whom exhibited signs of osteoporosis, Herzberg et al.[132] compared serum and urinary zinc levels before and after 6 and 12 months of treatment with estrogen replacement therapy (ERT) consisting of conjugated estrogens (0.625 mg) and medroxyprogesterone acetate (5 mg). They observed a "consistent negative association . . . between changes in bone mineral density and urinary zinc excretion in the osteoporosis group" and an association between ERT and "reduced excretion of zinc, magnesium, and hydroxyproline in the elevated zinc excretion group." In particular, urinary zinc excretion decreased 35% after 3 months and 26% after 1 year of ERT. In contrast, serum levels of zinc (as well as magnesium, calcium, and phosphate, but not alkaline phosphatase) "showed only negligible changes during ERT." Noting this significant decrease in urinary zinc excretion after 3 months of ERT, the authors concluded that this "change was more pronounced in women with osteoporosis and elevated zinc excretion" and was associated with changes in bone metabolism rather than variation in diet.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing exogenous estrogen preparations may consider the potential value of coadministering zinc, with the effect and rationale varying for different populations using estrogen for different purposes. In women using OCs, coadministration of a multimineral/multivitamin formulation containing zinc, as well as vitamin B_6 and folic acid, may reduce adverse effects of the medication, including nutrient depletion. The probability that such nutritional support will be beneficial is generally greater in patients with compromised nutritional intake. Women treated with ERT may derive benefit against osteoporotic tendencies with concomitant zinc, particularly if they have compromised nutrient intake and signs if osteoporosis. The use of concomitant zinc at a physiologic dosage level, 15 to 40 mg elemental zinc daily, is generally safe and unlikely to produce any clinically significant adverse effects. Moreover, in women receiving concomitant androgen therapy, the addition of zinc may enhance therapeutic outcomes. Further research through well-designed and adequately powered clinical trials may be warranted to establish risk factors and parameters of benefit to shape clinical guidelines for integration of zinc and other nutrients into therapeutic strategies using exogenous estrogens.

Histamine (H_2) Receptor Antagonists and Related Antacids and Gastric Acid–Suppressive Medications

Evidence: Famotidine (Pepcid RPD, Pepcid, Pepcid AC), ranitidine (Zantac).
Similar properties but evidence lacking for extrapolation: Nizatidine (Axid, Axid AR); combination drug: ranitidine, bismuth, and citrate (Tritec).
Similar properties but evidence indicating no or reduced interaction effects: Cimetidine (Tagamet, Tagamet HB).
Extrapolated, based on similar properties:
Antacids: Aluminum carbonate gel (Basajel), aluminum hydroxide (Alternagel, Amphojel); combination drugs: aluminum hydroxide, magnesium carbonate, alginic acid, and sodium bicarbonate (Gaviscon Extra Strength Tablets, Gaviscon Regular Strength Liquid, Gaviscon Extra Strength Liquid); aluminum hydroxide and magnesium hydroxide (Advanced Formula Di-Gel Tablets, Co-Magaldrox, Di-Gel, Gelusil, Maalox, Maalox Plus, Mylanta, Wingel); aluminum hydroxide, magnesium trisilicate, alginic acid, and sodium bicarbonate (Alenic Alka, Gaviscon Regular Strength Tablets); calcium carbonate (Titralac, Tums); magnesium hydroxide (Phillips' Milk of Magnesia MOM); combination drugs: magnesium hydroxide and calcium carbonate (Calcium Rich Rolaids); magnesium hydroxide, aluminum hydroxide, calcium carbonate, and simethicone (Tempo Tablets); magnesium trisilicate and aluminum hydroxide (Adcomag trisil, Foamicon); magnesium trisilicate, alginic acid, and sodium bicarbonate (Alenic Alka, Gaviscon Regular Strength Tablets); combination drug: sodium bicarbonate, aspirin, and citric acid (Alka-Seltzer).
Proton pump inhibitors: Esomeprazole (Nexium), lansoprazole (Prevacid, Zoton), omeprazole (Losec, Prilosec), pantoprazole (Protium, Protonix, Somac), rabeprazole (AcipHex, Pariet).

Interaction Type and Significance

≈≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, Not Requiring Professional Management**

Probability:
2. Probable

Evidence Base:
○ **Preliminary** to
◉ **Emerging**

Effect and Mechanism of Action

The solubility of the diverse zinc salts is affected by pH, which may vary between pH 1 and 7 under various physiological conditions in the stomach. Zinc absorption is optimal at an intragastric pH of 3 or less.[1] Thus, by reducing gastric acid secretion, H_2 blockers (as well as proton pump inhibitors, and possibly antacids) can exert both direct and indirect effects on the absorption of zinc and result in depletion over time.

Through its important role in the healthy function of mucous membranes and recovery from injury, zinc supports the repair of damaged gastric tissue.

Research

The basic physiological premises of gastric pH environment effects on zinc absorption are generally agreed on, but research-based evidence into the clinical implications of this interaction, although consistent, is limited. Using a rodent model, Pinelli et al.[133] found that cimetidine and nizatidine may reduce zinc absorption by decreasing gastric acid secretion and can deplete zinc levels in the prostate gland. In a series of experiments involving 16 healthy subjects, Sturniolo et al.[134] compared the effects of inhibition of gastric acid secretion by ranitidine and cimetidine on zinc absorption. First, they performed a zinc tolerance test (ZTT, with $ZnSO_4$, 220 mg orally), then administered cimetidine (1 g daily for 3 days), and observed decreased zinc absorption. Next, they administered

oral doses of ranitidine (300 mg) daily for 6 days, 3 days before testing and 3 days during the test; they also administered 500 mg cimetidine to these subjects. Overall, they observed that the "areas under the plasma concentration curves for zinc were significantly reduced after ranitidine . . . , but not after cimetidine administration. Gastric acid was also reduced after ranitidine, but not after cimetidine (500 mg) administration, suggesting that gastric acid secretion plays a role in the regulation of zinc absorption in man."[134] In a two-way, four-phase, crossover study involving 10 healthy subjects (five males and five females), Henderson et al.[1] investigated the effect of intragastric pH on zinc absorption. After a 9-hour fast, they administered a single oral dose of 50 mg elemental zinc as the acetate or the oxide salt and under either high or low intragastric pH conditions while continuously monitoring intragastric pH using a Heidelberg capsule pH detector-transmitter. "During the high pH phases, single oral doses of famotidine 40 mg oral suspension were administered before the zinc to raise the intragastric pH above 5. Intragastric pH < or = 3 was maintained in the low pH phases." They found that the "highest zinc plasma concentrations occurred with the acetate salt at a low intragastric pH, while the lowest plasma concentrations occurred with the oxide salt at a high intragastric pH." Subsequently, in vitro tests verified the importance of pH to the dissolution of these salts.[1]

Notably, numerous clinicians and researchers have reported benefits for gastric tissue damaged by ulceration. In a double-blind trial involving 18 patients with benign gastric ulcers and no evidence of zinc deficiency, Frommer[135] found that subjects administered zinc sulfate (220 mg orally three times daily) "had an ulcer healing rate three times that of patients treated with placebo," and that "complete healing of ulcers occurred more frequently in the patients taking zinc." These findings suggest that zinc may have independent therapeutic value in the treatment of individuals with gastric ulcer disease and related conditions, and that coadministration might provide synergistic effects.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing H_2 blockers (as well as proton pump inhibitors or antacids) are advised to coadminister elemental zinc, 50 to 75 mg daily (preferably as the acetate), to prevent the probable adverse effect of zinc depletion with chronic suppression of gastric acid.

Loop Diuretics

Bumetanide (Bumex), ethacrynic acid (Edecrin), furosemide (Lasix), torsemide (Demadex).

Interaction Type and Significance

≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**

Probability:
4. Plausible or
3. Possible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

The use of loop diuretics may result in increased urinary excretion of zinc.

Research

In a small, randomized trial, Wester[136] compared urinary zinc excretion in nine patients during treatment with bendroflumethiazide, chlorthalidone, and hydrochlorothiazide with that in nine patients treated with bumetanide, furosemide, and triamterene. He observed that in patients receiving loop diuretics, "urine zinc concentration diminished and the total amount of zinc excretion increased much less than during therapy with the thiazides." Based on these preliminary findings, the author concluded that "the observed increased urinary losses of zinc deserve further attention."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing a loop diuretic are advised to consider preliminary data suggesting that these medications may deplete zinc through increased urinary excretion. The risk of clinically significant zinc deficiency has not been established, but the probability of adverse effects is greater in individuals with compromised nutrient intake and concomitant medications that adversely affect zinc status. Dietary intake of zinc is often inadequate and zinc status impaired in many populations likely to be prescribed diuretics, such as patients with heart failure. Pending further research, medically supervised coadministration of zinc at a moderate dosage level, 40 to 80 mg elemental zinc once daily, is advisable as generally safe, unlikely to produce any clinically significant adverse effects, and potentially beneficial. Monitoring serum copper periodically and coadministering low-dose copper (e.g., 1-3 mg/day) are judicious means of guarding against zinc-induced copper deficiency with long-term zinc administration.

Metronidazole, Vaginal

Metronidazole, Vaginal (MetroGel-Vaginal)

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
4. Plausible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

The reported antitrichomonal properties of zinc sulfate appear to combine with metronidazole to produce an additive or synergistic interaction exerting greater therapeutic effect. No specific mechanism of action has been established.

Research

In a retrospective case analysis, Houang et al.[137] reported the successful treatment of four patients with chronic recurrent trichomoniasis, without evidence of reinfection, using a combination of "zinc sulfate douching (1%) followed by a metronidazole 500 mg suppository per vaginale twice daily and 200 to 400 mg three times a day orally. The douching and suppository were used prophylactically for 3 nights after menstruation for some months." These clinicians found that the addition of zinc sulfate douche greatly increased therapeutic efficacy in four patients "who had a history of 4 months to 4 years of culture-positive symptomatic trichomoniasis and received a variety of therapies before referral" and for whom vaginal metronidazole treatment alone had been ineffective. All four subjects remained asymptomatic and exhibited normal results in clinical and laboratory examinations at 2 to 5 months after treatment.

Further research with well-designed and adequately powered clinical trials may be warranted to confirm the efficacy of a combination zinc sulfate douche and metronidazole regimen in the treatment of vaginal trichomoniasis, as well as vaginal infection involving other organisms.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating women with vaginal trichomoniasis, especially recurrent or recalcitrant, are advised to consider concomitant prescription of zinc sulfate douche (1%) with metronidazole gel suppository. Adverse effects from zinc or from the combined intervention are unlikely to be greater than those associated with metronidazole alone, and the synergistic effect from coadministration may hasten or potentiate the treatment.

Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

COX-1 inhibitors: Diclofenac (Cataflam, Voltaren), combination drug: diclofenac and misoprostol (Arthrotec), diflunisal (Dolobid), etodolac (Lodine), fenoprofen (Dalfon), furbiprofen (Ansaid), ibuprofen (Advil, Excedrin IB, Motrin, Motrin IB, Nuprin, Pedia Care Fever Drops, Provel, Rufen); combination drug: hydrocodone and ibuprofen (Reprexain, Vicoprofen); indomethacin (indometacin; Indocin, Indocin-SR), ketoprofen (Orudis, Oruvail), ketorolac (Acular ophthalmic, Toradol), meclofenamate (Meclomen), mefenamic acid (Ponstel), meloxicam (Mobic), nabumetone (Relafen), naproxen (Aleve, Anaprox, Naprosyn), oxaprozin (Daypro), piroxicam (Feldene), salsalate (salicylic acid; Amigesic, Disalcid, Marthritic, Mono Gesic, Salflex, Salsitab), sulindac (Clinoril), tolmetin (Tolectin).
COX-2 inhibitor: Celecoxib (Celebrex).

Nutrient Interference

Probability: **4. Plausible**

Evidence Base: ○ **Preliminary**

Nutrient Depletion

Probability: **4. Plausible** or **3. Possible**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Low zinc levels may be associated with inflammatory conditions such as rheumatoid arthritis (RA).[138] Anti-inflammatory agents such as NSAIDs may increase zinc excretion and contribute to zinc depletion.[138,139]

Although not fully elucidated, zinc and other metals may complex with some NSAIDs to decrease absorption and bioavailability of both agents.[138,140] Other mechanisms are also probable but unknown.

Research

Data from human studies indicate that NSAIDs can increase urinary zinc excretion but differ as to whether serum zinc levels, a marginally accurate marker, may reflect these alterations. Elling et al.[139] conducted a study using healthy volunteers to assess the effect of naproxen, as a representative NSAID, on zinc metabolism. They observed a "significant increase in the urinary zinc excretion rate" in subjects administered naproxen, "with a mean increase in the order of 35%," which fell toward normal at the end of treatment and returned to normal after withdrawal of naproxen. Notably, the "serum zinc concentration was virtually unchanged" during the treatment period. Although noting that the mechanism by which naproxen induces hyperzincuria was "not known" at the time, the authors suggested that increased zinc excretion could result from "protein binding interaction or a direct renal action of naproxen implying a decrease in the maximum tubular reabsorption capacity (Tmax)." They concluded that trials of longer duration, particularly involving patients with RA, "are needed, however, in order to evaluate the possibility of a zinc depletion."[139] That same year (1980), Balogh et al.[138] investigated total plasma zinc levels in patients with RA being treated with a variety of medications. They found "significantly lower zinc levels in patients with rheumatoid arthritis on nonsteroidal anti-inflammatory drugs than in patients on levamisole and penicillamine." Moreover, zinc levels "correlated positively with serum albumin, and there was an inverse correlation between zinc levels and both ESR and globulin concentration in all rheumatoid patients." The authors concluded that their findings "support the hypothesis that low plasma zinc level in rheumatoid arthritis is one of the nonspecific features of inflammation."[138]

Dendrinou-Samara et al.[140] conducted in vitro experiments that demonstrated the formation of complexes between anti-inflammatory medications and Zn(II), as well as other metal ions. In particular, they synthesized and characterized complexes of "Zn(II), Cd(II) and Pt(II) metal ions with the anti-inflammatory drugs, 1-methyl-5-(p-toluoyl)-1H-pyrrole-2-acetic acid (Tolmetin), alpha-methyl-4-(2-methylpropyl) benzeneacetic acid (Ibuprofen), 6-methoxy-alpha-methylnaphthalene-2-acetic acid (Naproxen) and 1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-indole-3-acetic acid (indomethacin)." They noted that "antibacterial and growth inhibitory activity is higher than that of the parent ligands."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Health care professionals are advised to consider coadministration of zinc when providing care to individuals using NSAIDs or other anti-inflammatory agents on a chronic basis for the treatment of inflammatory conditions such as RA. Broad and specific data indicate that these patients are at increased risk of compromised zinc status because of their nutrient intake and pathophysiological changes, and that these agents may further deplete zinc. Such depletion patterns may not be easily detected through standard laboratory tests; for example, serum zinc may not predictably reveal zinc deficiency in tissue or cells. Specific evidence-based research is lacking to confirm efficacy, but the use of concomitant zinc at physiologic levels, 15 to 40 mg elemental zinc daily, is generally safe and unlikely to produce any clinically significant adverse effects. However, separation of intake by at least 2 hours is prudent given the limited but pharmacologically reasonable data suggesting the possibility of chelate formation with simultaneous intake.

Penicillamine

Penicillamine (D-penicillamine; Cuprimine, Depen).
Extrapolated, based on similar properties: Tetrathiomolybdate (investigational).

Effect and Mechanism of Action

Wilson's disease is a rare but potentially fatal autosomal recessive inherited disease of copper accumulation in the liver in which a defect in a copper-transport adenosine triphosphatase results in a failure of biliary excretion of excess copper.

Zinc and penicillamine can both be used in the treatment of individuals with Wilson's disease because of their effects of lowering copper levels, although by different mechanisms.[141-143] Zinc produces its unique anticopper action by inducing intestinal cell metallothionein, which then forms a mucosal block, preventing copper absorption and increasing copper excretion in the stool. "Because this mechanism blocks not only the absorption of food copper but the reabsorption of large amounts of endogenously secreted copper, zinc serves to remove copper from the body as well as prevent its reaccumulation."[142] On the other hand, penicillamine can effectively increase urinary excretion of copper and reverse positive copper balance through its action as a chelating drug, but is also known for adverse effects.

However, the simultaneous intake of zinc and penicillamine may result in impaired efficacy and nutrient depletion. When ingested close together, penicillamine and zinc, as a supplement or through zinc-rich or zinc-enriched foods, may bind, resulting in reduced bioavailability of both agents. Moreover, penicillamine, through its chelating effect, may cause an unintentional increase in urinary excretion of zinc, along with the intended copper excretion. Effects will vary with mode of administration; the maximal plasma penicillamine concentrations achieved with oral penicillamine are only one-fifth that achieved by injection.[144]

Research

Different forms of zinc have been used in the treatment of Wilson's disease, with zinc acetate used directly and zinc sulfate combined with penicillamine. Anderson et al.[141] reviewed trials and case reports concerning zinc acetate as maintenance therapy in patients initially treated with a chelating agent. They concluded: "Although studies evaluating large populations are lacking, zinc therapy has demonstrated exceptional safety and efficacy over a period of 40 years.... Zinc acetate is an effective maintenance therapy for patients with Wilson's disease." They further noted that with its "negligible toxicity, compared with that of previously approved treatments, zinc acetate is considerably safer than other treatments and can be used during pregnancy and for the treatment of presymptomatic patients." They cautioned, however, that "data do not support its use as monotherapy in patients with acute neurologic or hepatic disease."

Li et al.[143] conducted a clinical trial, with long-term follow-up (4-11 years) of 31 children, investigating combined therapy with "large-dose zinc sulfate and low-dose penicillamine" in children with Wilson's disease (hepatolenticular degeneration, HLD). During the active phase of treatment, they treated symptomatic pediatric patients with "large-dose zinc sulfate (100-150 mg, <6 yr; 150-200 mg, 6-8 yr; 200-300 mg, 9-10 yr; 300 mg, >10 yr; 3 times a day) in addition to low-dose penicillamine (8-10 mg/kg/d)." Presymptomatic patients received zinc sulfate alone, as did patients receiving maintenance therapy when clinical improvement was achieved. They reported that "blood concentrations of copper were persistently lower than normal" and that "urine copper excretion of 24 hours was significantly lower than that before the combined therapy in all patients," and it became normal in five cases (16%) after 6 months of treatment, and in 26 cases (84%) after 1 to 2 years of treatment. They also observed "higher blood concentrations of zinc" in 20 subjects (65%), with "higher urine zinc excretion ... in 25 cases (81%) once or more times during the therapy." They concluded that combined treatment with "large-dose zinc sulfate and low-dose penicillamine is an effective, safe and cheap treatment for children with HLD."

Thus, the limited data from clinical trials indicate that zinc and penicillamine can be safely and effectively used together as part of a long-term strategy in the treatment of copper accumulation diseases, particularly Wilson's disease, but that timing and dosage need to be adjusted at different phases of the treatment based on patient response.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating individuals with Wilson's disease may enhance clinical outcomes and reduce adverse effects through implementation of an integrative therapeutic strategy combining zinc and chelating agents such as penicillamine or tetrathiomolybdate (investigational). Oral zinc sulfate and zinc acetate have both been used successfully in clinical trials. However, many clinicians consider zinc sulfate an inferior form with limited bioavailability. Zinc acetate, on the other hand, has superior bioavailability but may require a prescription, mainly because of its use in treating Wilson's disease. In all cases, the timing of zinc administration will depend on patient condition and response, with some researchers and clinicians relying primarily on chelating agents during the more severe stages of treatment and using zinc primarily for maintenance once a patient has stabilized or in presymptomatic patients. Zinc and copper chelators are best used sequentially rather than simultaneously because copper chelators also chelate zinc, although they are sometimes used concurrently. In all cases, separation of intake by at least 2 hours is recommended to minimize the risk of the two agents complexing and becoming less bioavailable. Close clinical management by trained and experienced health care professionals, with supervision and regular monitoring, is essential. Further study is warranted and probable given the body of evidence and practice supporting coadministration and sequential administration.

Potassium-Sparing Diuretics

Evidence: Amiloride (Midamor), triamterene (Dyrenium).
Similar properties but evidence indicating no or reduced interaction effects: Amiloride combination drug: amiloride and hydrochlorothiazide (Moduretic).
Similar properties but evidence lacking for extrapolation: Spironolactone (Aldactone), spironolactone and hydrochlorothiazide (Aldactazide), triamterene and hydrochlorothiazide (Dyazide, Maxzide).

Evidence Base: ○ **Preliminary** to ◉ **Emerging**

Coadministration Risk

Probability: **4. Plausible** or **3. Possible**

Evidence Base: ▽ **Mixed,** ○ **Preliminary**

Effect and Mechanism of Action

Potassium-sparing diuretics demonstrate varied effects on zinc metabolism. Amiloride may induce zinc accumulation (and potential toxicity) by significantly reducing zinc excretion; however, this effect appears to be dose related and may not compensate for zinc loss caused by concomitant diuretics such as hydrochlorothiazide. Conversely, triamterene appears to increase urinary zinc excretion in the short term and may cause depletion over time. Overall, the mechanisms by which thiazide diuretics affect zinc metabolism are incompletely known, although their blocking of reabsorption in the distal tubule is a plausible extrapolation from the known mechanism involving magnesium.

Research

Wester[145] conducted several studies of experiments investigating the effects of various diuretics on urinary zinc excretion and tissue levels of zinc. In one paper he reported that 2 weeks of treatment with triamterene increased urinary zinc excretion by 18% compared with baseline.[136]

The situation with amiloride is both more complicated and less clear in its implications. In a review, Reyes et al.[146] suggest that a 10-mg dose of amiloride can significantly reduce urinary zinc excretion, but not 5 mg. Such an effect introduces the potential for excess zinc accumulation, although the effect is dose related, and the patient population is characterized by a relatively high incidence of inadequate zinc nutriture. Moreover, decreased zinc excretion does not inherently result in elevated zinc levels, given the homeostatic regulation of zinc absorption and the dynamic metabolic processes of zinc pools.

Two trials have investigated the effects of an amiloride-thiazide combination on zinc metabolism and nutriture, with mixed conclusions. Golik et al.[146a] compared serum zinc levels and urinary zinc excretion in 15 patients with essential hypertension taking a combination of hydrochlorothiazide and amiloride as chronic monotherapy, eight patients maintained with hydrochlorothiazide alone, and eight control subjects. Although "serum zinc values were statistically comparable in all three groups," they found that "urinary zinc excretion was abnormally elevated in the two patient groups." These authors concluded that, at least "in the dosage used, amiloride did not have a zinc-sparing effect." That same year (1987), Verho et al.[146b] published a paper reporting their findings in a double-blind, parallel-group study comparing the effects of hydrochlorothiazide (50 mg) plus amiloride (5 mg) once daily versus piretanide (6 mg) once or twice daily on serum levels of zinc and other trace elements over 3 months in subjects with mild to moderate hypertension. They concluded that 3 months' therapy with "a thiazide-potassium sparer diuretic combination is safe without producing any disturbances in the serum levels of trace elements," based on the findings that urinary zinc excretion stayed within normal levels. The use of serum zinc to evaluate effects on zinc status in both studies limits the utility of conclusions based on their findings, but suggests that the depleting effects of the thiazide agent and the zinc-conserving effects of the potassium-sparing diuretic may neutralize each other in some cases. Nevertheless, the effects of these agents on tissue zinc stores and zinc pools deserve further research to determine the long-term effects of these drugs in a patient population with a relatively high incidence of subclinical zinc deficiency.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing potassium-sparing diuretics are advised to monitor zinc status closely in all patients. However, early symptoms of zinc deficiency, such as hypogeusia (decreased taste sensation), hyposmia (decreased olfactory sensation), diminished male sexual function, increased incidence of infections, slower wound healing, and white spots in fingernails, may be more useful than relying on monitoring of zinc levels in serum or elsewhere, because consensus is lacking as to an adequate laboratory standard for accurate assessment. Patients should be instructed to report any such occurrences. Triamterene can readily cause zinc depletion in the short term and with chronic use and, despite some suggestions to the contrary, the risk of zinc depletion with amiloride cannot be excluded, particularly in individuals with potential risk of marginal zinc status and increased susceptibility to zinc toxicity. Thus, coadministration of zinc at physiologic levels, 15 to 40 mg elemental zinc daily, may be indicated in patients receiving long-term triamterene and possibly other potassium-sparing diuretics.

The risk of zinc accumulation with amiloride use remains controversial, but close supervision and regular monitoring are always judicious in patients at greater risk for zinc toxicity, such as occurs with pregnancy, alcoholism, or renal insufficiency. Inherently, the probability of such risk being clinically significant would be greater in patients taking amiloride at a higher dose. Combining a thiazide diuretic with amiloride to mitigate its possible adverse effects may not provide a safe and simple remedy because these drugs deplete not only zinc but also other nutrients. Moreover, the mechanisms through which thiazide diuretics affect the metabolism of zinc and other minerals have not been fully elucidated, and the physiological effects of this proposed "pharmacological balancing act" have not been confirmed by substantive evidence from high-quality clinical trials.

Radiotherapy

Radiotherapy, external radiation therapy.

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Loss or alteration of taste sensation is a common adverse effect of radiation therapy in oncology patients, particularly in those receiving external radiotherapy (ERT) to the head and neck region. Zinc is known to play a central role in taste sensation, as well as the synergistic function of olfaction. Coadministration of zinc during and after radiotherapy may mitigate adverse effects on taste sensation and support recovery from such damage.

Research

Limited research indicates that administration of zinc during or after radiotherapy may reduce adverse effects of radiation on taste perception, but that benefit is less likely in patients experiencing loss of taste perception resulting from hemodialysis. Ripamonti et al.[147] investigated the administration of oral zinc sulfate in preventing and correcting taste abnormalities for four taste qualities in cancer patients before, during, and after receiving radiotherapy to the head and neck region. They randomized 18 patients to receive either zinc sulfate tablets (45 mg per dose) or placebo three times daily "at the onset of subjective perception of taste alterations during the course of ERT and up to 1 month after ERT termination." After noting that "taste acuity for one or more taste qualities was already impaired before ERT," they reported that "taste alterations were experienced at least once for a minimum of 3 of the 8 measured thresholds by 100% of the patients" during ERT treatment, and that "33.3% of the patients became aware of some alteration within the first week of treatment." When treatment (or placebo) was initiated after appearance of such adverse effects, they found that "patients treated with placebo experienced a greater worsening of taste acuity during ERT treatment compared with those treated with zinc sulfate," and that "one month after ERT was terminated, the patients receiving zinc sulfate had a quicker recovery of taste acuity than those receiving placebo." In particular, "statistically significant differences between the two groups emerged for urea detection and sodium chloride recognition thresholds during ERT treatment and for sodium chloride, saccharose, and hydrogen chloride recognition thresholds after the termination of ERT treatment." These researchers concluded that "pharmacologic therapy [with zinc] is effective and well tolerated; it could become a routine in clinical practice to improve the supportive care of patients with taste alterations resulting from head and neck cancer."[147]

In relevant but unrelated research, Matson et al.[148] conducted a double-blind, randomized, placebo-controlled study involving 15 stable hemodialysis patients. They found that zinc sulfate, 220 mg daily for 6 weeks, "does not improve the disturbance of taste perception," particularly for the sour modality, in hemodialysis patients.

These two preliminary studies indicate that further research is warranted through well-designed clinical trials investigating the mechanisms of action in preventing and recovering taste sensation, how that differs in relation to iatrogenic cause, and whether prophylactic zinc coadministration might produce better outcomes than reactive prescribing.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians administering radiotherapy, particularly to patients with head and neck cancers, may prevent or reverse alteration or loss of taste sense, which often occurs as a result of such therapy, through concomitantly prescribing 40 to 60 mg elemental zinc daily. Use of zinc at this dosage level is unlikely to produce any adverse effects, if complemented with low-dose copper, or interfere with conventional oncological therapies.

Tetracycline Antibiotics

Evidence: Demeclocycline (Declomycin), minocycline (Dynacin, Minocin, Vectrin), tetracycline (Achromycin, Actisite, Apo-Tetra, Economycin, Novo-Tetra, Nu-Tetra, Sumycin, Tetrachel, Tetracyn); combination drugs: chlortetracycline, demeclocycline and tetracycline (Detreclo); bismuth, metronidazole and tetracycline (Helidac).

Extrapolated, based on similar properties: Oxytetracycline (Terramycin).

Similar properties but evidence indicating no or reduced interaction effects: Doxycycline (Atridox, Doryx, Doxy, Monodox, Periostat, Vibramycin, Vibra-Tabs).

Interaction Type and Significance

◇◇ **Impaired Drug Absorption and Bioavailability, Precautions Appropriate**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

◇≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**

Probability: **3. Possible** or **2. Probable**

Evidence Base: ● **Consensus**

Effect and Mechanism of Action

Tetracycline and some related antibiotics tend to form relatively insoluble chelates with zinc salts (and other divalent and trivalent metal ions) and thereby impair absorption and therapeutic activity of both agents.[149,150] In contrast to other members of the tetracycline class, doxycycline and zinc do not appear to interact to a clinically significantly degree.[151]

Research

The scientific literature on the effects of zinc on bioavailability of tetracycline antibiotics is generally considered as constituting a well-documented consensus, although specific research from human trials is limited. Penttila et al.[151] conducted a crossover study involving seven volunteers to compare the effect of zinc sulfate on the absorption of tetracycline and doxycycline. They reported that when a single dose of zinc sulfate (45 mg elemental zinc) was given simultaneously with tetracycline hydrochloride (500 mg) or doxycycline chloride (200 mg), the "serum concentration of tetracycline, the area under the serum tetracycline concentration-time curve and the excretion of tetracycline in urine were reduced by about 30%... from the respective control values," but the "absorption of doxycycline was not influenced significantly." Overall, they concluded that the "clinical significance of the zinc-tetracycline interaction seems to be of limited importance." Andersson et al.[152,153] published similar findings regarding intestinal absorption of zinc in their study of eight healthy volunteers administered 50 mg elemental

zinc orally. That same year (1976), Mapp and McCarthy[154] found that "absorption of 250 mg phosphate-potentiated tetracycline hydrochloride was reduced by 75% when administered concurrently with 220 mg zinc sulphate."

Minimal research has focused on the effects of tetracycline on zinc absorption and clinical implications of long-term use. In rodent studies, administration of tetracycline was reported to result in increased elimination rate of zinc, which could originate in zinc-tetracycline interactions in blood plasma. However, after "using clinical data relative to fasting subjects as taken from the literature" to perform computer simulations of zinc-tetracycline interactions in the GI fluid, Brion et al.[158] concluded that "no significant effect can be expected from tetracyclines on the distribution of zinc in plasma at the usual therapeutic levels." Nevertheless, the authors added that "zinc-tetracycline interactions have been found to be determining factors for the bioavailabilities of the metal as well as of the antibiotic in the gastrointestinal fluid." No studies have been conducted to determine the effects of chronic or repeated tetracycline antibiotics on zinc status and function in humans.

Weimar et al.[156] and Michaelsson et al.[157] demonstrated that patients with dermatitis herpetiformis, acne, psoriasis, and Darier's disease have low epidermal zinc concentrations. Notably, "mean serum zinc concentration was, however, significantly decreased only in men with dermatitis herpetiformis."[156]

Clinical Implications and Adaptations

Physicians prescribing tetracycline antibiotics are advised to ask patients about their supplement use and to tell them to separate intake of zinc supplements, multimineral formulation, and zinc-rich food (as well as other mineral intake) by at least 2 hours before or 4 hours after the medication. Such precautions would also prevent the potential depletion of zinc by the tetracyclines by avoiding chelate formation. In patients being treated for acne, especially inflammatory acne, coadministration of 30 to 45 mg elemental zinc daily, as zinc acetate, citrate, gluconate, or other highly bioavailable forms, may be indicated and can be efficacious, assuming compliance with intake separation. Zinc sulfate has been less effective and associated with greater incidence of adverse effects.[84,156-159] When both agents are indicated, consider prescribing doxycycline, a noninteracting tetracycline.

Thiazide Diuretics

Bendroflumethiazide (bendrofluazide; Naturetin); combination drug: bendrofluazide and propranolol (Inderex); benzthiazide (Exna), chlorothiazide (Diuril), chlorthalidone (Hygroton), cyclopenthiazide (Navidrex); combination drug: cyclopenthiazide and oxprenolol hydrochloride (Trasidrex); hydrochlorothiazide (Aquazide, Esidrix, Ezide, Hydrocot, HydroDiuril, Microzide, Oretic), hydroflumethiazide (Diucardin), methyclothiazide (Enduron), metolazone (Zaroxolyn, Mykrox), polythiazide (Renese), quinethazone (Hydromox), trichlormethiazide (Naqua).

Similar properties but evidence lacking for extrapolation: Spironolactone (Aldactone); combination drugs: hydrochlorothiazide and amiloride (Moduretic); hydrochlorothiazide and captopril (Acezide, Capto-Co, Captozide, Co-Zidocapt); hydrochlorothiazide and enalapril (Vaseretic); hydrochlorothiazide and lisinopril (Prinzide, Zestoretic); hydrochlorothiazide and losartan (Hyzaar); hydrochlorothiazide and metoprolol (Lopressor HCT); spironolactone and hydrochlorothiazide (Aldactazide); triamterene and hydrochlorothiazide (Dyazide, Maxzide).

See also Amiloride in Potassium-Sparing Diuretics.

Interaction Type and Significance

≈≈ Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management

Probability:
3. Possible

Evidence Base:
○ Preliminary

Effect and Mechanism of Action

Thiazide diuretics can increase urinary zinc excretion and result in zinc loss with either single-dose or long-term use.[146,160] Long-term thiazide therapy may cause significant zinc depletion, particularly in individuals with preexisting impaired zinc status, compromised nutrient intake, or medical conditions susceptible to zinc deficiency.[136,161] The mechanism of thiazide diuretics' effect on zinc is poorly understood, but these agents act primarily on the initial portion of the distal convoluted tubule in the nephron; hormone-mediated processes may also be involved.

Research

In a small, randomized trial, Wester[136] compared urinary zinc excretion in nine patients during treatment with bendroflumethiazide, chlorthalidone, and hydrochlorothiazide with that in nine patients treated with bumetanide, furosemide, and triamterene. He observed that in patients receiving thiazide diuretics, "the zinc concentration rose by 30% and the total amount of zinc excretion increased by 60%." Based on these preliminary findings, the author concluded that "the observed increased urinary losses of zinc deserve further attention."

In a review, Reyes[160] cautioned that the probability of a clinically significant zinc deficiency with thiazide diuretics is greater in pregnant women and individuals with hepatic cirrhosis, diabetes mellitus, GI disorders, renal insufficiency, and alcoholism, that is, conditions associated with diminished total body zinc levels. Likewise, in related research, Golik et al.[110] determined that individuals with type 2 diabetes mellitus and congestive heart failure "excrete larger amounts of zinc, which may eventually lead to zinc deficiency." These findings bear directly on the data relating to hypertensive medications, given the use of diuretics for heart failure and the high incidence of comorbid hypertension among these patient populations.

The combination of amiloride with a thiazide combination, as a means of mitigating the adverse effects of both agents on zinc metabolism and nutriture, is discussed in the Potassium-Sparing Diuretics section. Similarly, the concomitant use of hydrochlorothiazide and ACE inhibitors may further exacerbate zinc loss; this interaction is reviewed in Captopril, Enalapril, and related Angiotensin-Converting Enzyme (ACE) Inhibitors.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing thiazide diuretics are advised to coadminister zinc (50-100 mg elemental zinc daily) to compensate for possible drug-induced zinc loss and prevent zinc depletion. Monitoring for zinc deficiency is appropriate but is compromised by the limited sensitivity of laboratory assessment in accurately detecting depletion of zinc at the tissue level. Advise patients to watch for signs of zinc depletion, especially those at greater risk for compromised nutrient intake or other factors likely to impair zinc status.

Coadministration of folic acid, magnesium, potassium, and calcium may also be appropriate to prevent adverse effects from thiazide diuretic on the physiological levels and functions of these nutrients and to advance the broader therapeutic goals of enhancing cardiovascular health.

Valproic Acid and Related Anticonvulsant Medications (AEDs)

Evidence: Divalproex semisodium, divalproex sodium (Depakote), sodium valproate (Depacon), valproate semisodium, valproic acid (Depakene, Depakene Syrup).
Similar properties but evidence lacking for extrapolation: Carbamazepine (Carbatrol, Tegretol), clonazepam (Klonopin), clorazepate (Tranxene), ethosuximide (Zarontin), ethotoin (Peganone), felbamate (Felbatol), fosphenytoin (Cerebyx, Mesantoin), levetiracetam (Keppra), mephenytoin, mephobarbital (Mebaral), methsuximide (Celontin), oxcarbazepine (GP 47680, oxycarbamazepine, Trileptal), phenobarbital (phenobarbitone; Luminal, Solfoton), phenytoin (diphenylhydantoin; Dilantin, Phenytek), piracetam (Nootropyl), primidone (Mysoline), topiramate (Topamax), trimethadione (Tridione), vigabatrin (Sabril), zonisamide (Zonegran).

Interaction Type and Significance

≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**

Probability: **4. Plausible**

Evidence Base: ▽ **Mixed**

Effect and Mechanism of Action

Valproic acid (VPA) can alter zinc and copper homeostasis and may cause depletion of either or both minerals, not necessarily reflected in serum levels. The anticonvulsive activity of VPA on the brain may be "mediated through its effect on the metabolism of Zn in the brain and the concomitant changes in the activity of the zinc-dependent enzymes glutamic acid decarboxylase and carbonic anhydrase."[162]

Research

Animal and human studies of VPA's effect on zinc status have produced mixed findings. Using a rodent model, Hurd et al.[163] found that VPA administration for 1 week produced significant depletion of plasma levels of zinc, as well as selenium. In a study of 15 children with primary epilepsy receiving long-term VPA treatment, Lerman-Sagie et al.[162] found that serum and urine levels of zinc and copper levels were within normal limits, but erythrocyte zinc content was significantly lower than controls matched for age and gender. The authors interpreted their findings as suggesting that the antiseizure effect of valproate may be related to and/or mediated by its effect on zinc-dependent CNS enzymes. Subsequently, Kaji et al.[164] investigated measured serum zinc and copper levels in epileptic children treated with VPA and/or other antiepileptic drugs (AEDs). They found that in "contrast to the reported results of animal experiments, serum Zn levels were not altered in patients with VPA treatment." Notably, patients "treated with VPA monotherapy had significantly lower levels of serum Cu" than normal controls, as did those "treated with VPA in addition to some other AED." Those "treated with AEDs except for VPA" exhibited serum copper concentrations "not statistically different from those of control subjects." However, in a later trial involving 51 children with epilepsy, Sozuer et al.[165] observed that patients treated with VPA, as monotherapy or in combination with carbamazepine, exhibited significantly lower levels of serum zinc than in the two control groups, consisting of seven untreated epileptic and 12 normal children. Because serum zinc and copper "concentrations of the untreated epileptics were not significantly different from those of normal controls," the authors concluded that "serum trace metal homeostasis may be affected by AED therapy, but not by the convulsive disorder itself."

Reports

In a letter, Simpson and Bryce-Smith[166] reported cutaneous manifestations of zinc deficiency during treatment with anticonvulsants.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing VPA, as monotherapy or in combination with other AEDs, will want to be watchful for deficiencies of zinc and numerous other key nutrients, especially in children and women of childbearing age. Given the lack of reliable measures of zinc deficiency, it is particularly important to instruct patients to be alert to signs of zinc deficiency, such as alterations in taste or smell sensation and increased frequency of infections. Although specific evidence-based research is lacking to confirm drug-induced depletion or efficacy of coadministration, the use of concomitant zinc at a low dosage level, 30 to 50 mg elemental zinc daily, would be prudent and is generally safe and unlikely to produce any clinically significant adverse effects. In children a dose of 10 mg elemental zinc twice daily is typical but can vary depending on the child's age and weight. Complementary daily copper, 1/15 to 1/30 the dose of zinc, would prevent copper deficiency resulting from the medication or the zinc intake.

Warfarin and Related Oral Vitamin K Antagonist Anticoagulants

Anisindione (Miradon), dicumarol, ethyl biscoumacetate (Tromexan), nicoumalone (acenocoumarol; Acitrom, Sintrom), phenindione (Dindevan), phenprocoumon (Jarsin, Marcumar), warfarin (Coumadin, Marevan, Warfilone).

Interaction Type and Significance

◇◇ **Impaired Drug Absorption and Bioavailability, Precautions Appropriate**

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

◇ **Adverse Drug Effect on Nutritional Therapeutics, Strategic Concern**

Probability: **4. Plausible**

Evidence Base: ▽ **Mixed** or ○ **Preliminary**

Effect and Mechanism of Action

Zinc, as well as other minerals such as iron and zinc, may bind with warfarin or dicumarol and reduce bioavailability of the medication.[167,168] Formation of such complexes might also reduce zinc absorption and bioavailability and could potentially interfere with the effectiveness of oral zinc as a preventive or therapeutic agent.

Research and Reports

Despite recurrent descriptions of this interaction as "well documented," a search of the scientific literature provides no clinical trials or substantive case reports directly investigating or confirming evidence from in vitro experiments or extrapolations from interactions involving iron, calcium, or other minerals. Although reasonably predictable from a

pharmacokinetics perspective, research into this area would be valuable given the large number of patients using nutritional supplements that contain zinc or other metals.

Clinical Implications and Adaptations

The chemistry of common mineral nutrients binding warfarin is well founded, but the frequency of occurrence is uncertain, its nature remains unclear, and conclusive evidence of the clinical significance of this interaction is lacking. Nevertheless, physicians prescribing warfarin are advised to recommend to patients that they separate warfarin administration from intake of zinc (or iron or magnesium) supplements by at least 2 hours. Regardless, physician-patient communication is especially important in the event that individuals undergoing anticoagulant therapy are taking zinc or any other mineral supplements. Nutritional support, including zinc, may be indicated in many patients likely to be on warfarin therapy given the high incidence of inadequate zinc nutriture among elderly and institutionalized individuals. Regular monitoring of international normalized ratio (INR) is critical so that warfarin levels can be adjusted accordingly when concomitant intake is deemed appropriate.

Zidovudine (AZT) and Related Nucleoside or Nonnucleoside (Analog) Reverse-Transcriptase Inhibitors (NRTIS or NNRTIS) Antiretroviral Agents

Evidence: Zidovudine (azidothymidine, AZT, ZDV, zidothymidine; Retrovir).
Extrapolated, based on similar properties: Azidothymidine combination drugs: abacavir, lamivudine, and zidovudine (Trizivir); zidovudine and lamivudine (Combivir); didanosine (ddI, dideoxyinosine; Videx), dideoxycytidine (ddC, zalcitabine; Hivid), lamivudine (3TC, Epivir), stavudine (D4T, Zerit), tenofovir (Viread).

Interaction Type and Significance

≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**

Evidence Base: **◉ Emerging**

Effect and Mechanism of Action

Zinc plays a central role in many immune functions, including T-cell division, maturation, differentiation, and function; lymphocyte response to mitogens; programmed cell death of lymphoid and myeloid origins; gene transcription; and biomembrane function. Thymulin, a zinc-bound hormone, and Cu/Zn superoxide dismutase, as well as congenital or acquired zinc deficiencies, are associated with immune abnormalities and increased susceptibility to infectious diseases.[169] AZT may deplete zinc (and other nutrients). Populations likely to have a high incidence of HIV infection may also be more likely to exhibit compromised zinc status, possibly due to malnutrition, progression of the pathology, or excessive ejaculation.[170-173] "AIDS subjects suffer from reduced zinc bioavailability, more severe in stage IV than in stage III."[174]

Zidovudine may deplete plasma zinc levels; conversely, adequate zinc levels may enhance therapeutic response to AZT treatment.[175] Zinc deficiency may diminish drug effectiveness because zidovudine requires thymidine kinase, a zinc-dependent enzyme, for conversion to its active triphosphate form.[170,173] Notably, individuals with HIV infection, particularly later stages of AIDS, tend to exhibit elevated cooper levels.[176]

Research

In a 1991 longitudinal study involving 37 HIV-positive participants, 15 treated with ZDV (AZT, 500-1200 mg/day) and 22 serving as untreated, CD4 level–matched controls, Baum et al.[175] found significantly decreased mean plasma levels of zinc (and copper) in a "large proportion" of AZT-treated subjects after 12 months of antiviral therapy. Hematological and plasma nutrient levels were similar in both groups before treatment, but after therapy, "drug-treated subjects demonstrated alterations in hematological and nutritional parameters." The authors noted that the "level of plasma zinc appeared to be particularly important in maintaining immune function in the ZDV-treated group. Whereas ZDV-treated subjects with adequate zinc levels displayed a significant increase in the response of peripheral blood lymphocytes to mitogens, this enhancement was not demonstrated in zinc-deficient, ZDV-treated participants or in untreated individuals whose lymphocyte response significantly declined over time, despite adequate zinc status." The authors concluded that their findings "reveal a zidovudine-induced effect on nutritional parameters, indicating the importance of monitoring nutritional status with drug therapeutic regimens."[175] Subsequent papers by Baum et al.[169] and Bogden et al.[176] have emphasized the key physiological roles of zinc and the importance of zinc status in HIV infection, providing evidence that compromised nutritional and antioxidant status begins early in HIV-1 infection and may contribute to disease progression.

Although some survey data indicate that higher zinc intake may be associated with worse outcomes in HIV-positive individuals (regardless of AZT therapy), other trials suggest a potential synergistic benefit from coadministration in patients treated with AZT. In a survey of 281 HIV-positive homosexual/bisexual men, Tang et al.[177] reported that increased intake (from food and supplements) of "zinc was monotonically and significantly associated with an increased risk of progression to AIDS." In a follow-up paper the authors reported that "any intake of zinc supplements, however, was associated with poorer survival" and suggested that further "studies are needed to determine the optimal level of zinc intake in HIV-1-infected individuals."[178] Conversely, in a study investigating the relationship between zinc deficiency and survival in HIV-positive homosexual men, Campa et al.[179] found that higher zinc levels were associated with better immune function and higher CD4+ cell counts, while zinc deficiency was associated with greater incidence of HIV-related mortality. Subsequently, Mocchegiani et al.[174] conducted a clinical trial involving 17 AZT-treated stage III subjects with generalized lymphadenopathy and 12 stage IV/subgroup C1 AIDS patients, with 18 stage III subjects with generalized lymphadenopathy and 10 stage IV/subgroup C1 subjects treated only with AZT serving as controls. Stage III and stage IV/C1 patients administered zinc sulfate (200 mg daily for 30 days) exhibited an "increase or a stabilization in the body weight and an increase of the number of CD4+ cells and the plasma level of active zinc-bound thymulin," and the "frequency of opportunistic infectious episodes in the 24 months following entry into the

study was reduced after zinc supplementation in stage IV C1 subjects (11 infections versus 25 in controls) and delayed in stage III zinc-treated subjects (1 infection/24 months versus 13 infections/24 months in controls)." Notably, the beneficial effect of zinc on opportunistic infections was "restricted to infections due to *Pneumocystis carinii* and *Candida*, whereas no variations have been observed in the frequencies of *cytomegalovirus* and *toxoplasma* infections." The authors concluded that these data "may support the benefit of zinc as an adjunct to AZT therapy in AIDS pathology."[174]

In a randomized, double-blind, placebo-controlled trial involving 96 children with HIV-1 infection in South Africa, Bobat et al.[180] found that administering 10 mg daily of elemental zinc, as sulfate, reduced watery diarrhea significantly and lowered the incidence of pneumonia (compared to placebo), without adversely affecting (i.e., increasing) plasma HIV-1 viral load. In a randomized controlled trial involving 159 HIV-infected adults in Peru, with at least a 7-day history of diarrhea, Carcamo et al.[181] found that 2 weeks of treatment with 50 mg zinc twice daily does not reduce or eliminate persistent diarrhea in adults infected with HIV. The authors added: "Longer treatment or follow-up beyond 2 weeks might have revealed treatment benefit.... Among children, however, benefits of zinc supplementation on diarrhea have been evident after the fourth day of supplementation."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating HIV-infected individuals with AZT or related antiretroviral regimens should always assess nutritional status, particularly dietary intake and use of antioxidant and other supplements, and consider coadministration of zinc, selenium, glutathione/*N*-acetylcysteine, and other nutrients that may be beneficial. Multiple factors, including the underlying pathology, concomitant health and lifestyle factors, comorbid conditions, and the multiple medications often used, strongly suggest high susceptibility to compromised nutritional status, which may be further exacerbated by drug-induced nutrient depletion patterns.

Moderate-dose to high-dose zinc, 50 to 100 mg elemental zinc daily, may counter preexisting deficiency, reduce effects of drug-induced depletion, and facilitate the activity of AZT. Coadministration of 1 to 2 mg of copper may be appropriate (but may be contraindicated if serum/plasma levels are already high) to neutralize the potential risk of adverse effects on the immune system from the long-term zinc. Laboratory assessment of zinc status may be less than ideal, but regular monitoring of the nutritional and metabolic status of such patients is essential, including instructing the patient to be attentive to signs of possible zinc deficiency. Clinical management of HIV-positive patients using multiple treatment modalities in an individualized and evolving integrative strategy requires close collaboration and regular coordination among health care professionals trained and experienced in conventional pharmacology and nutritional therapeutics.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Acetylsalicylic Acid (Aspirin) and Related Anti-Inflammatory Analgesic Medications

Acetylsalicylic acid (acetosal, acetyl salicylic acid, ASA, salicylsalicylic acid; Arthritis Foundation Pain Reliever, Ascriptin, Aspergum, Asprimox, Bayer Aspirin, Bayer Buffered Aspirin, Bayer Low Adult Strength, Bufferin, Buffex, Cama Arthritis Pain Reliever, Easprin, Ecotrin, Ecotrin Low Adult Strength, Empirin, Extra Strength Adprin-B, Extra Strength Bayer Enteric 500 Aspirin, Extra Strength Bayer Plus, Halfprin 81, Heartline, Regular Strength Bayer Enteric 500 Aspirin, St. Joseph Adult Chewable Aspirin, ZORprin); combination drugs: ASA and caffeine (Anacin); ASA, caffeine, and propoxyphene (Darvon Compound); ASA and carisoprodol (Soma Compound); ASA, codeine, and carisoprodol (Soma Compound with Codeine); ASA and codeine (Empirin with Codeine); ASA, codeine, butalbital, and caffeine (Fiorinal); ASA and extended-release dipyridamole (Aggrenox, Asasantin). Salsalate (Salicylic acid; Amigesic, Disalcid, Marthritic, Mono Gesic, Salflex, Salsitab).
Indomethacin (Indometacin; Indocin, Indocin-SR).
See also Nonsteroidal Anti-inflammatory Drugs (NSAIDs); similar mechanisms involved.

In a 1982 letter, Ambanelli et al.[182] reported that intake of 3 g aspirin daily can induce changes in serum and urinary zinc, observable beginning 3 days after initiation of aspirin; indomethacin was also implicated. Such an effect would generally be considered reasonably predictable based on scientific knowledge of the respective properties and activities of these agents. Further research would be warranted to determine the risks, clinical implications, and responsible countermeasures in individuals using aspirin chronically.

Conversely, in vitro experiments conducted by Kim et al.[183] demonstrated attenuation of Zn^{2+} neurotoxicity by aspirin attributed to the prevention of synaptically released Zn^{2+} entry into neurons, primarily through voltage-gated Ca^{2+} channels (VGCC), which can mediate pathological neuronal death. The authors noted that "aspirin derivatives lacking the carboxyl acid group did not reduce Zn^{2+} neurotoxicity" and interpreted these findings as suggesting "that aspirin prevents Zn^{2+}-mediated neuronal death by interfering with VGCC, and its action specifically requires the carboxyl acid group." Further research may be warranted to determine potential clinical implications of these observations.

Bile Acid Sequestrants

Evidence: Cholestyramine (Locholest, Prevalite, Questran).
Extrapolation: Colesevelam (WelChol), colestipol (Colestid).

Cholestyramine and other bile acid sequestrants are known to bind a multitude of nutrients, including zinc and other key minerals, in the gut, impairing bioavailability to the degree that depletion and deficiency may occur. However, research is limited and primarily derived from animal studies. Using a rodent model to investigate alterations in calcium, magnesium, iron, and zinc metabolism by cholestyramine, Watkins et al.[184] found that, compared to controls, cholestyramine-fed rats exhibited "a lower net positive balance for magnesium, iron, and zinc" and "a decreased urinary zinc." The authors hypothesized: "Alterations in calcium, magnesium, and zinc metabolism might be explained by inadequate vitamin D absorption from the intestine followed by an increased secretion of parathyroid hormone." Regardless of the limited human research, concern for adverse effects on nutrient status in patients being treated with bile acid sequestrants is widespread among clinicians and researchers, and concomitant support with broad-spectrum multivitamin-mineral supplements is considered judicious, with the caveat that intake needs to be at least 2 hours before or 4 hours after the medication.

Bisphosphonates

Alendronate (Fosamax), clodronate (Bonefos, Ostac), etidronate (Didronel), ibandronate (Bondronat, Boniva), pamidronate (Aredia), risedronate (Actonel), tiludronate (Skelid), zoledronic acid (Zometa).

With simultaneous intake, numerous minerals, including zinc, may bind with bisphosphonates and impair the absorption of all agents involved.

Although reasonable and consistent with present pharmacokinetic knowledge concerning other minerals, evidence from clinical trials directly substantiating the chelation interaction between zinc and bisphosphonates is lacking.

Preliminary data indicate other probable interactions between bisphosphonates and zinc. Adami et al.[185] found that IV bisphosphonate administration "induced an acute-phase response (APR) irrespective of the underlying disease, manifested by a fall in circulating lymphocyte number and serum zinc concentration and in a rise in C-reactive protein." Notably, in postmenopausal women with osteoporosis, alendronate significantly reduces the concentrations of urinary zinc. Thus, comparison of zinc excretion and biochemical markers of bone remodeling have been proposed in the assessment of the effects of alendronate and calcitonin on bone in postmenopausal women with osteoporosis.[186]

Health care professionals treating individuals on bisphosphonate therapy for osteoporosis should inform patients of this probable chelation interaction and instruct them to separate oral intake, ingesting the zinc (and other minerals) 1 hour before or 2 hours after the bisphosphonate.

Zinc chelation may play a role in novel cancer therapies involving use of bisphosphonates to chelate zinc and thereby inhibit matrix metalloproteinases (MMPs), a family of zinc-dependent proteinases involved in the degradation of the extracellular matrix, a process on which cancer metastasis is believed to depend.[187-189] In an in vitro experiment, Boissier et al.[190] reported that bisphosphonates inhibited MMP proteolytic activity by breast and prostate carcinoma cells, and that this inhibitory effect of bisphosphonates on MMP activity was completely reversed in the presence of excess zinc. These areas of zinc-bisphosphonate interaction are currently being investigated.

Clofibrate and Related Fibrates

Evidence: Clofibrate (Atromid-S).
Related: Bezafibrate (Bezalip), ciprofibrate (Modalim), fenofibrate (Tricor, Triglide, Lofibra), gemfibrozil (Apo-Gemfibrozil, Lopid, Novo-Gemfibrozil).

In addition to its antihyperlipidemic activity, clofibrate is known to alter serum protein patterns, including proteins associated with key minerals.[191] Using a rodent model, Powanda et al.[192] detected a "significant decrease in plasma zinc . . . after the rats were fed the 1.25% clofibrate diet for 1 week," as well as "a significant decrease in hepatic zinc." However, clofibrate did not affect the plasma concentration of α_2-macroglobulin, although it did "selectively decrease the plasma concentration of two trace metal carrier proteins, transferrin and ceruloplasmin." The authors noted that the observed reduction in the hepatic concentration of zinc "may merely be the result of a redistribution to achieve a new systemic equilibrium." However, they also speculated that "the depression in plasma zinc reflects the marked decrease in transferrin, which is known to bind zinc, or is caused by the displacement of zinc from albumin by clofibrate." Thus, despite offering several possible explanations for these findings, they declared that the "decrease in plasma zinc remains to be explained."[192]

Further research into the interaction between clofibrate and zinc is not readily discoverable through a standard search of the scientific literature. Follow-up research may be warranted given the increased knowledge of the manifold roles of zinc that has emerged since publication of this single paper.

Cyclosporine

Cyclosporine (Ciclosporin, cyclosporin A, CSA; Neoral, Sandimmune, SangCya).

Several secondary reference texts have declared, without citing specific and substantive evidence, that zinc should not be administered concomitantly with cyclosporine or other immunosuppressant drug regimens because of its "immunostimulant" activity. Emerging knowledge of the complex and nuanced function of zinc as a modulator of immune function in its interplay within the dynamic network and signaling model, such as suggested in the work of Candace Pert, Michael Ruff, and other pioneers of psychoneuroimmunology, as well as the continually shifting nature of its distribution, suggest that a simple characterization of zinc as "stimulating" the immune system is unlikely to offer a comprehensive explanation for the diverse effects observed in clinical practice and research settings. Consequently, a blanket contraindication of zinc coadministration appears speculative without substantive human research findings or qualified case reports documenting adverse effects, preferably with a clear elucidation of the mechanism(s) of action. Further research is warranted, with clinical supervision and monitoring being critical in the meantime, as always with patients undergoing any immunosuppressive therapy.

Dopamine Receptor Antagonists

Metoclopramide (Reglan), olanzapine (Symbyax, Zyprexa).

In vitro studies with zinc suggest that it appears to modulate antagonist drug interactions with the D_2 dopamine receptor and the dopamine transporter.[193,194] However, direct evidence, from clinical trials or substantive case reports, of a clinically significant adverse effect on the therapeutic activity of drugs that rely on dopamine receptor antagonists is lacking at this time. In an experimental setting, Schetz et al.[194] demonstrated "the effect of zinc on the binding of D_1- and D_2-selective antagonists to cloned dopamine receptors and show that the inhibition by zinc is through a dose-dependent, reversible, allosteric, two-state modulation of dopamine receptors." They found that zinc "exerts a low-affinity, dose-dependent, EDTA-reversible inhibition of the binding of subtype-specific antagonists primarily by decreasing the ligands' affinity for their receptors," and suggested that "the mechanism of zinc inhibition appears to be allosteric modulation of the dopamine receptor proteins." Based on data from multiple investigators indicating that zinc "retards the functional effects of antagonist at the D_2L receptor in intact cells," research findings have been interpreted to "suggest that synaptic zinc may be a factor influencing the effectiveness of therapies that rely on dopamine receptor antagonists."[193,194] These in vitro studies suggest that zinc may interact with drugs that rely on dopamine receptor antagonists and indicate that further clinical research is warranted to determine the character and clinical significance of such an interaction.

Gillin et al.[195] (1982) studied patients with acute and chronic schizophrenia, on or off treatment with various major tranquilizers, looking for significant deviations from normal in concentrations of zinc or copper in serum, urine, or gastric fluid, in serum ceruloplasmin or in hair zinc. Although depletion of body zinc and increases in brain

copper have been associated with severe changes in mentation and personality, they found no differences. Research has already been reviewed to indicate that measurement of zinc deficiencies is unreliable and tentative, with multiple pools existing in the body and their concentrations not necessarily relating to levels found in plasma, urine, gastric fluid, or hair. Insufficient data exist even to guide zinc clinic trials because schizophrenia may be a heterogenous condition. Ten years later, Andrews[196] (1992) suggested that male transmission of risk, the parental age effect, racial differences in birth seasonality, the disturbed gender ratios in the offspring of schizophrenic mothers, and the association between diabetes and schizophrenia are explained by changes to zinc homeostasis. The primary site of action of zinc deficiency was proposed to be the putative ZFY sex-determining system. Zinc deficiency was also linked to other mental disorders. During the 1970s, Pfeiffer and Bacchi[197] reported successful outcomes in 95% of more than 400 patients diagnosed with pyrroluria-type schizophrenia using vitamin B_6 and zinc.

EDTA

EDTA (Ethylenediaminetetraacetic acid).

In vitro experiments suggest that concomitant use with zinc might increase the cytotoxicity of cisplatin in the presence of EDTA, compared with cisplatin alone.[198]

Ethambutol

Ethambutol (Myambutol).

Ethambutol is an antibiotic used therapeutically in the treatment of tuberculosis that can affect trace-metal metabolism through its action as a chelating agent. Using a rodent model, Solecki et al.[199] investigated the effects of ethambutol on tissue concentrations and balance of zinc, copper, iron, and manganese. They observed that ethambutol "produced significant decreases in heart copper, kidney zinc, plasma zinc, and liver copper and zinc not due to the associated reduced food intake." No human trials or qualified case reports have appeared in the scientific literature to confirm this possible interaction in humans or determine its clinical significance.

Folic Acid

Folic acid, folinic acid.

In addition to its availability as orally administered nutritional supplements, folic acid at doses greater than 1 mg is available in tablet and injectable forms with a prescription. Despite preliminary reports and unsubstantiated statements in the secondary literature indicating that folic acid administration can reduce blood levels of zinc, two reviews of folic acid safety concluded that such an adverse effect is improbable.[200,201] Pending confirmation by more substantive evidence, physicians prescribing folic acid at supplemental levels or in prescription doses do not need to recommend compensatory coadministration of zinc. Nevertheless, monitoring serum/plasma levels and watching for clinical signs of zinc insufficiency (e.g., decreased smell/taste) would be prudent when folic acid is administered at higher therapeutic levels for an extended time; in cases where long-term zinc supplementation is added, low-dose copper may also be indicated.

Hydralazine

Hydralazine (Apresoline).

The scientific literature provides very limited data on the potential interaction between zinc and hydralazine, and available research is convoluted by numerous confounding variables. Fjellner[202] described a 58-year-old woman with long-standing hypertension and leg ulcers and mild joint involvement of 3 years, being treated for 6 years with hydralazine (30-200 mg/day) and propranolol (120-640 mg/day) as well as thyroxine and several other medications, who developed multisystemic manifestations of a lupus erythematosus–like syndrome within 1 week after introduction of oral zinc sulfate (200 mg three times daily). Clinical improvement, including healing of the oral ulcers and remission of the fever and abdominal distress, occurred on cessation of zinc intake. Notably, however, the patient's condition persisted until all the medications except thyroxine were discontinued. Clearly, attributing a multifactorial aggravation in a single case to an interaction between zinc and hydralazine would be speculative, at best, and extrapolating that to a generalized pharmacological phenomenon would be an ill-founded misrepresentation of the very limited data available, particularly since hydralazine is known to be capable of producing drug-induced lupus on its own. It is also notable that the dose of zinc in this case report was extremely high. Vigilance for similar case reports may be warranted so that a pattern of incidence and common risk factors might be elucidated.

Interferon Alfa (Interferon Alpha)

Interferon alfa (Interferon alpha; Alferon N, Intron A, Roferon-A); combination drug: interferon alfa-2b and ribavirin (Rebetron).

Necrolytic acral erythema is a rare skin disorder categorized as a form of necrolytic erythema, along with acrodermatitis enteropathica (congenital disorder of zinc metabolism), and apparently linked to infection with hepatitis C virus. Khanna et al.[203] described the case of a "43-year-old black woman who presented with a 4-year history of tender, flaccid blisters localized to the dorsal aspect of her feet," which was subsequently diagnosed as necrolytic acral erythema and chronic hepatitis C. Although her serum zinc level was normal, she was "successfully treated with interferon alfa-2b and zinc." In a review of the literature on necrolytic acral erythema, these authors found four cases (of seven) "treated with variable success using oral zinc sulfate and amino acids, whereas 2 were successfully treated with interferon alfa," even though "serum zinc levels were normal in all patients in whom they were measured." The dose of oral zinc sulfate administered ranged from 60 to 440 mg per day and "was effective to varying degrees" in five (of eight) patients, including the authors' original patient. In focusing on the interferon-zinc synergy they noted that in one case, "interferon alfa alone resulted in almost complete clearance of lesions," whereas in the two other cases, "the addition of interferon alfa to oral zinc resulted in total clearance." The authors interpreted the collective evidence from their case report and literature review to suggest that "interferon alfa alone may be sufficient to treat necrolytic acral erythema or may enhance the effect of oral zinc."[203] Further research appears to be warranted to investigate the mechanism(s) involved in this possible interaction, elucidate any relationship to zinc deficiency or faulty zinc metabolism as well as other forms of necrolytic erythema, and establish clinical guidelines, if confirmed to be effective.

Nystatin

Nystatin (Mycostatin, Nilstat, Nystex).

In a single in vitro study, Grider and Vazquez[204] found that nystatin, a sterol-binding drug known to inhibit potocytosis, inhibited zinc uptake in both normal and acrodermatitis enteropathica (AE) fibroblasts. They noted that "reduced cellular uptake of zinc was associated with its internalization, not its external binding." The authors concluded that "nystatin exerts

its effect on zinc uptake by reducing the velocity at which zinc traverses the cell membrane, possibly through potocytosis," and that "the AE mutation also affects zinc status by reducing zinc transport." These preliminary findings, if confirmed by further research, suggest that individuals on nystatin therapy, especially for an extended period, may be at risk for zinc depletion and that zinc coadministration may be indicated; the potentially beneficial effects of zinc on immune function may provide added benefit, particularly in the presence of compromised zinc status.

NUTRIENT-NUTRIENT INTERACTIONS

Antioxidant Nutrients

An emerging body of evidence largely indicates that zinc in conjunction with an antioxidant network strategy, particularly one emphasizing lutein and anthocyanoside-rich plants such as bilberry *(Vaccinium myrtillus)*, may prevent or slow the advance of macular degeneration.[205,216] Research continues in this important area.

Calcium and Calcium-Based Antacids

Numerous reports suggest that calcium at high doses (e.g., >1500 mg/day) may significantly impair zinc absorption. Animal research suggests interference with zinc uptake by intestinal mucosa due to counter–ion binding to mucus glycoproteins as a possible mechanism.[217] However, this possible effect appears to be of limited clinical significance, especially if calcium is taken with food, which may improve the gastric environment. Further, the effect of calcium on gut pH, whether as supplement or as calcium-based antacids, can interfere with zinc absorption by altering gastric pH away from optimal (i.e., low) pH range, as noted in the discussion of Histamine (H_2) Receptor Antagonists.

In an early experiment, Pecoud et al.[218] investigated the effect of foodstuffs on the absorption of zinc sulfate by administering single doses of zinc sulfate to healthy young volunteers, either in the fasting state or with various types of meals. They observed that "dairy products (milk and cheese) and brown bread decreased zinc absorption, as indicated by a significant drop in peak serum zinc levels." Subsequently, however, other researchers have found that increases of calcium, within dietary sources or as calcium carbonate or hydroxyapatite, did not significantly alter zinc balance and retention in the presence of meals.[219,220]

In a study involving nine patients on hemodialysis and 11 controls, Hwang et al.[221] studied the effects of calcium carbonate and calcium acetate, both known phosphate binders, on intestinal zinc absorption by measuring 1-hour and 2-hour serum zinc levels after oral administration of 50 mg of elemental zinc as zinc gluconate, with or without concomitant administration of 2 g calcium carbonate (800 mg elemental calcium) or 3 g calcium acetate (750 mg elemental calcium). They observed that intestinal zinc absorption after an oral zinc challenge decreased in patients on hemodialysis with concomitant administration of calcium acetate, but calcium carbonate did not decrease intestinal zinc absorption in either group.

In contrast to these earlier studies, later research has used physiological doses of zinc and calcium more typical of the amounts found in meals. For example, in an experiment involving nine healthy female college-age students, Argiratos and Samman[222] observed that the plasma zinc AUC after simultaneous ingestion of zinc with calcium carbonate and calcium citrate (600 mg elemental calcium) was significantly lower than that after ingestion of zinc alone, reflecting a 72% and 80% reduction, respectively, in zinc absorption. The authors concluded that the "decrease in zinc absorption following the ingestion of zinc with different forms of calcium suggests that an antagonistic competition occurred between the minerals and that elemental calcium is the inhibiting factor."

In a trial involving 44 hemodialysis patients, Hwang et al.[223] found that short-term and long-term uses of calcium acetate (containing 25.35 mmol elemental calcium daily) did not change hair and serum zinc concentrations over an 8-month period. The authors noted that even though daily calcium did "not significantly interfere with zinc absorption and storage" in hemodialysis (HD) patients, the "comparable hair zinc content in the presence of decreased serum zinc concentrations indicates that the metabolic processing of zinc in HD patients is different from that of normal individuals."

Overall, the available data indicate that an antagonistic relationship between calcium and zinc may adversely affect zinc bioavailability with simultaneous intake in a fasting state, but that the presence of substantial food or separation of intake can minimize any such pharmacokinetic interaction. The resulting recommendation that patients ingest their zinc with a meal, but preferably not one high in phytates (e.g., grains, soy), or at least 2 hours away from calcium preparations is consistent with other known pharmacological principles and optimal clinical practices.

Copper

The complex interaction between these two pivotal minerals is well documented and generally agreed on but often oversimplified. Zinc significantly interferes with copper absorption and thus can cause copper deficiency or be therapeutic in the treatment of individuals with Wilson's disease.[47,48,52,224-227] Zinc induces intestinal cell metallothionein, which binds copper and prevents its transfer into blood; eventually the intestinal cells die and slough, taking the trapped copper with them in the stool, thus preventing intestinal absorption of copper. However, the combined presence of these two minerals in Cu/Zn superoxide dismutase indicates that they do not relate only competitively. Such key complementary activity, along with the whole arena of metalloenzymes, is only beginning to become the subject of research with practical clinical significance.

Prolonged intake of supplemental zinc, particularly longer than 1 month, warrants compensatory copper supplementation, typically 1 to 3 mg daily, except for individuals with Wilson's disease or when the therapeutic strategy employs zinc as an anticopper agent. The typical recommended ratio of zinc to copper is 10:1 to 20:1, with relatively higher zinc allowable in some elderly patients, who, at least in the United States, tend to have a history of ingesting water carried through copper pipes, and who tend to have a diet higher in copper and lower in zinc. Baseline serum copper and zinc levels, although not necessarily reflective of various metabolic pools, can nevertheless be useful in guiding the relative dosing of these two minerals where appropriate. Copper preparations should be taken at least 2 hours apart from zinc preparations.

L-Cysteine

The luminal phase of zinc intestinal absorption may be mediated by low-molecular-weight substances, with amino acids being primary candidates for this role through the formation of complexes with zinc. A significant proportion of plasma zinc exists complexed with amino acids. Zinc absorption may be enhanced by concomitant intake of the amino acid L-cysteine through the formation of a complex.[228] However,

one study found that L-cysteine stimulates zinc uptake in rat but not in human erythrocytes.[229] Notably, L-cysteine may also help mobilize and excrete copper. Some clinicians suggest that L-cysteine is a CNS excitotoxin with potentially damaging effects, but that coadministration with zinc may block such effects. Pending further research, this potential interaction is most accurately characterized as speculative.

Folic Acid

See section in Theoretical, Speculative, and Preliminary Interactions Research.

Glutamine and Probiotic Bacterial Flora

Many clinicians experienced in natural medicine and integrative therapeutics place major importance on the phenomenon of excessive intestinal permeability, also known as *dysbiosis* or "leaky gut syndrome," diagnosed by alterations in the differential absorption of lactulose and mannitol. This syndrome can occur in patients with Crohn's disease or other GI pathology and potentially in large segments of the population whose gut ecology has been disrupted by the adverse effects of antibiotics and other stressors on healthy intestinal flora. Probiotics and glutamine are among the core treatment elements typically used in therapeutic regimens to restore gut wall integrity and normal intestinal flora colonization.

Sturniolo et al.[230] administered oral zinc sulfate (110 mg three times a day) for 8 weeks to 12 patients "with quiescent Crohn's disease who had been in remission for at least 3 months and had increased intestinal permeability on two separate occasions within the last 2 months." They found that "the lactulose/mannitol ratio was significantly higher before supplementation than after," and that during follow-up 12 months later, 10 patients "had normal intestinal permeability and did not relapse; of the remaining two who had increased intestinal permeability, one relapsed." The authors concluded that their "findings show that zinc supplementation can resolve permeability alterations in patients with Crohn's disease in remission" and that "improving intestinal barrier function may contribute to reduce the risk of relapse in Crohn's disease."

L-Histidine

Histidine is involved with the regulation of zinc levels. Both zinc and L-histidine are known competitors of intestinal copper uptake, and concomitant L-histidine intake may enhance the absorption of zinc.[231] Moreover, L-histidine can stimulate zinc uptake by erythrocytes.[229] In a study investigating zinc-dependent cognitive function, Keller et al.[232] found that coadministration of L-histidine during dietary zinc repletion improved short-term memory in zinc-restricted young adult male rats.

Iron

Interactions between iron and zinc appear to occur both during intestinal absorption and throughout the body after absorption. Iron and zinc may compete for absorption because of similarities in physicochemical properties and potentially shared absorptive pathways, such that bioavailability and therapeutic activity of both agents could potentially be reduced with simultaneous intake. Intestinal divalent metal transporter-1 (DMT1) has been proposed as a possible site, but others have noted that zinc is not transported by the DMT1.[233] This possible pharmacokinetic interaction can be difficult to manage clinically because iron and zinc deficiencies occur together in various populations and may have to be addressed concurrently, especially among women and children in developing countries. In a review of literature investigating the interplay between iron and zinc at the level of enterocyte and neural tissues, Kordas and Stoltzfus[233] reported complex and paradoxical findings but clear patterns of probability. Their in vitro research indicates that iron may inhibit zinc absorption in some cells at very high ratios of iron to zinc, but not vice versa. Consequently, they proposed "a shift in thinking about iron-zinc interactions from the level of enterocyte to other sites/systems in the body [such as the nervous system] that may be equally relevant for the outcome and interpretation of supplementation trials."

Various studies have reported diverse interactions between zinc and iron, depending on forms, preparation, and doses administered; concomitant intake; protocol design; subject life phase (e.g., pregnancy); and trace-element status of subjects. Solomons[234] observed that inorganic iron competed for absorption with zinc when given to adults in solution in ratios greater than two to one. However, iron did not significantly affect zinc absorption when they administered Atlantic oysters, providing 54 mg "organic" zinc (vs. inorganic zinc sulfate). Thus, "the evidence for competitive interaction of zinc and iron was strongest with nonheme iron and inorganic zinc."[235] In human experiments, Rossander-Hulten et al.[236] compared the effect of zinc on iron absorption both in solution and in a hamburger meal and observed no inhibitory effect, "suggesting different pathways for the absorption of zinc and iron." They did, however, find that an "intraluminal interaction may occur, because a fivefold excess of zinc to iron (15 mg Zn/3 mg Fe) reduced iron absorption by 56% when given in a water solution but not when given with a hamburger meal." Nevertheless, they noted that "fractional iron absorption is strongly dose dependent." Similarly, using a rodent model, Peres et al.[237] demonstrated that inhibition of zinc absorption by iron depended on their ratio and the deficiency/repletion status of each mineral in the animals. "Between 2:1 and 5:1 a dose dependent inhibition of zinc absorption occurred and reached a plateau beyond this ratio. In iron deficient animals no changes in zinc uptake, mucosal retention and absorption compared to normal animals occurred at ratio 2:1." Meadows et al.[238] studied the oral bioavailability of zinc in nonpregnant adults before and 24 hours after 2 weeks of oral administration of iron and folic acid. They found that "bioavailability was greatly reduced, and the shape of the plasma curves suggested that this was due to impairment of the intestinal absorption of zinc." The authors interpreted their findings as suggesting that "the reduced bioavailability of zinc occurs because of interelement competition in the bowel wall" and cautioned that this phenomenon "might induce zinc depletion." O'Brien et al.[239] reported that zinc absorption was significantly reduced in fasting pregnant Peruvian women administered inorganic iron or inorganic iron plus zinc, compared with nonsupplemented women. However, they also noted that plasma zinc concentrations were also lower in women administered only iron, compared with controls.

In contrast, other researchers observed smaller improvements in hemoglobin and serum ferritin concentrations in Indonesian children administered both iron and zinc than in children given iron alone.[240,241] Similarly, Donangelo et al.[242] found that concomitant zinc (22 mg daily as zinc gluconate and 100 mg iron daily as ferrous sulfate) can lower measures of iron status in nonanemic young women with low iron reserves. In reviewing the literature on interactive effects of iron and zinc on biochemical and functional outcomes in supplementation trials, Fischer Walker et al.[243] concluded that "zinc

supplementation alone does not appear to have a clinically important negative effect on iron status. However, when zinc is given with iron, iron indicators do not improve as greatly as when iron is given alone . . . . Although some trials have shown that joint iron and zinc supplementation has less of an effect on biochemical or functional outcomes than does supplementation with either mineral alone, there is no strong evidence to discourage joint supplementation."

Zinc is often combined with other nutrients, including iron, in the prevention and treatment of nutritional deficits and resulting health problems among impoverished infants and children, especially in nonindustrial societies. In a longitudinal, double-blind, placebo-controlled trial, Muñoz et al.[244] found that coadministration of zinc (20 mg/day), iron (20 mg/day), or the combination for 6 months improved indicators of vitamin A status, particularly higher plasma retinol and transthyretin, compared with placebo, in Mexican preschoolers.

Fortunately, analysis of these complex findings produces some clear and consistent clinical guidelines. The body of evidence indicates that clinically significant adverse pharmacokinetic interactions can be avoided by separating intake of iron and zinc by at least 2 hours, outside the context of meals, or minimized by ingesting the nutrients with a meal, particularly one containing meat, which tends to be rich in both iron and zinc. These guidelines are most important in individuals at risk for compromised nutrient status, of either mineral or generally, with particular concern in pregnant women being supplemented with iron and thus potentially increasing risk of adverse effects, including intrauterine growth retardation and congenital abnormalities related to exacerbated zinc deficiency.

Magnesium

Zinc may exert inhibitory effects on magnesium balance and magnesium absorption in humans.[245] Separating oral intact by at least 2 hours will generally mitigate any impairment of bioavailability of either mineral.

See also Histamine (H_2) Receptor Antagonists and related Antacids and Gastric Acid–Suppressive Medications.

Manganese

In experiments on competitive inhibition of iron absorption by manganese and zinc in humans, Rossander-Hulten et al.[236] found significant differences in the effect of the two minerals on manganese absorption, both in solution and in a hamburger meal. They observed that manganese "inhibited iron absorption both in solutions and in a hamburger meal" and that "fractional iron absorption is strongly dose dependent." Conversely, in "the same experiment with zinc, no inhibitory effect was observed, suggesting different pathways for the absorption of zinc and iron." However, an "intraluminal interaction may occur, because a fivefold excess of zinc to iron (15 mg Zn/3 mg Fe) reduced iron absorption by 56% when given in a water solution but not when given with a hamburger meal."[236] Thus, although the impact of manganese on zinc absorption appears to be significantly less than on iron availability, separating oral intact by at least 2 hours will generally mitigate any impairment of bioavailability of either mineral.

N-Acetylcysteine (NAC)

N-acetylcysteine (NAC), particularly with high doses administered intravenously, as used clinically for acetaminophen poisoning, can complex with zinc, possibly increasing zinc absorption but also increasing urinary zinc excretion.[246] Coadministration of zinc (and copper) may be prudent in individuals using NAC on a long-term basis.

Vitamin B_2 (Riboflavin)

Zinc absorption may be impaired in riboflavin deficiency. Supportive data are lacking to confirm this possible interaction.

HERB-NUTRIENT INTERACTIONS

Ashwagandha

Ashwagandha *(Withania somnifera)*, boswellia *(Boswellia serrata)*, turmeric *(Curcuma longa)*.

In a randomized, double-blind, placebo-controlled, crossover study in 42 patients with osteoarthritis, Kulkarni et al.[247] reported clinical efficacy, including a "significant drop in severity of pain . . . and disability score," after treatment with a herbomineral formulation containing roots of *Withania somnifera*, the stem of *Boswellia serrata*, rhizomes of *Curcuma longa*, and a zinc complex (Articulin-F). Although the contribution of zinc to the clinical efficacy observed cannot be determined with this research design, further research through well-designed and adequately powered clinical trials may be warranted.

Bloodroot

Bloodroot *(Sanguinaria canadensis)*.

Several studies have investigated and supported a synergistic interaction between zinc and sanguinaria in the treatment of plaque, halitosis, and gingivitis.[248-253]

Evening Primrose Oil

Evening Primrose Oil *(Oenothera biennis)*.

Weak evidence from preliminary research indicates that concomitant administration of zinc and evening primrose oil may be beneficial in the treatment if individuals diagnosed with attention deficit–hyperactivity disorder.[254]

The 257 citations for this monograph, as well as additional reference literature, are located under Zinc on the CD at the back of the book.

Arginine

Nutrient Name: Arginine.
Synonym: L-Arginine.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Antihypertensive medications Angiotensin-converting enzyme (ACE) inhibitors Potassium-sparing diuretics ⊕/✗/✗/⊕⊕	Possible additive effect on potassium levels, phosphorus levels, vascular dilation, and blood pressure from concomitant administration. Resultant tendency toward elevated potassium levels and lowered blood pressure could theoretically produce cardiovascular instability or therapeutic benefit, depending on patient variability, communication and compliance, and therapeutic strategy.	Well-managed coadministration possibly appropriate, with close supervision and regular monitoring.
Cyclosporine ☼	L-Arginine, as substrate for nitric oxide (NO) synthesis, may alter vasodilator mechanism(s), particularly NO blockade, possibly responsible for cyclosporine-induced vascular dysfunction, and by enhancing NO levels, decrease cyclosporine nephrotoxicity.	Coadminister, if appropriate. Close supervision and regular monitoring warranted.
Sildenafil Phosphodiesterase-5 inhibitors ⊕⊕	Vasodilation involved in erection requires NO and arginine is the precursor of NO synthesis. NO enables therapeutic action of sildenafil, which may be enhanced by arginine intake, especially in men with low levels or abnormal metabolism of NO.	Coadminister; consider evaluating NO status. Communication, observation, and occasional management appropriate.
Theophylline, aminophylline ⊕	Increased arginase activity and NO deficiency can contribute to airway reactivity. Arginine is substrate for NO synthesis. Preliminary evidence indicates that theophylline or aminophylline could theoretically create a beneficial additive or synergistic effect by reducing arginase activity and increasing arginine's availability to be converted to NO.	Coadminister, if appropriate. Close supervision and regular monitoring warranted.

NUTRIENT DESCRIPTION

Chemistry and Forms

Arginine is a complex amino acid often found at the active (or catalytic) site in proteins and enzymes because of its amine-containing side chain. With four nitrogen atoms per molecule, it is the most abundant nitrogen carrier in humans and animals.

Physiology and Function

Arginine's primary function is generally considered to be the transport, storage, detoxification, and excretion of nitrogen, in particular, and metabolism of protein, in general, through the urea cycle. Arginine is also the substrate for nitric oxide synthase and arginase, two important metabolic pathways. Nitric oxide (NO), a key vasodilator, neurotransmitter, and cell-signaling molecule, is formed by the three different nitric oxide synthases from the N-guanido terminal of the amino acid L-arginine and from molecular oxygen. Nitric oxide synthase (NOS) also converts arginine to citrulline. Arginase converts arginine to ornithine and urea. Arginase I and arginase II control the transformation of arginine into ornithine, which subsequently forms proline and polyamines, which exert multiple effects on connective tissue, smooth muscle, and mucus synthesis. The NOS and arginase pathways interfere with each other through substrate competition.

As the precursor to NO, arginine plays a key role in the circulatory and respiratory systems, particularly endothelial function, vasodilation, and airway physiology. Arginine also functions as a key immunomodulator, particularly increasing the number of T cells, enhancing T cell function, and supporting tissue regeneration. Recent studies have reported increases in arginase in conditions including reperfusion injury, asthma, psoriasis, arthritis, and human breast cancer. Helper T cell type 2 (Th2) cytokines induce arginase expression. During allergic inflammation, increased interleukin-4 (IL-4) and/or IL-13 expression results in increased expression of arginase and amplification of the arginase-dependent pathway, with concomitant suppression of NO generation. Furthermore, in relation to neuroendocrine function, arginine strongly influences adrenal and pituitary functions, especially through stimulation of catecholamines, norepinephrine, insulin and glucagon, prolactin, and growth hormone (GH). Lastly, arginine is involved in synthesis of spermine and spermidine, polyamines required for cell division and growth, and numerous aspects of reproductive function. Hepatic metabolism of arginine produces hydrogen ions (H^+).

Arginine is generally considered a conditionally essential amino acid because adult humans can generally synthesize it de novo from ornithine, glutamine, glutamate, and proline. However, arginine must be obtained through the diet during the juvenile period in humans and in those not synthesizing adequate amounts to meet metabolic demands, especially after acute trauma, burns, or surgery and during infections, chronic illness, or wound healing. In all situations, dietary intake remains the primary determinant of plasma arginine levels, since the rate of arginine biosynthesis does not increase to compensate for depletion or inadequate supply.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Arginine's central role in promoting NO formation forms the basis of its therapeutic effect in the treatment of cardiovascular disease, asthma, interstitial cystitis, female sexual dysfunction, and male erectile dysfunction. In particular, a growing body of research has focused on arginine's ability to induce vasodilation and improve endothelial function through its role as a substrate for NO synthesis. Arginine hydrochloride has been used

clinically in correcting severe metabolic alkalosis because of its high chloride content. Findings from preliminary double-blind trials indicate the efficacy of arginine in the treatment of acquired immunodeficiency syndrome (AIDS) cachexia, angina, congestive heart failure (CHF), endothelial function in type 1 diabetes, erectile dysfunction, hypertension, and other conditions. Arginine has also been used therapeutically to enhance several aspects of healthy function, including supporting wound healing and resistance to infection; elevating production of GH and related hormones; increasing exercise tolerance, lean muscle mass, and total strength; improving sperm motility and sexual vitality; and reducing low-density lipoprotein (LDL) cholesterol.

Historical/Ethnomedicine Precedent

Arginine has not been used historically as an isolated nutrient.

Possible Uses

Angina, athletic performance, burns, chronic renal failure, congestive heart failure, cystic fibrosis, enhancing formation of muscle mass, erectile dysfunction, female infertility (in vitro fertilization), gastritis, hepatic insufficiency, human immunodeficiency virus (HIV) support, hypercholesterolemia, hypertension, inflammatory bowel disease, immunity enhancement, intermittent claudication (intravenous only), interstitial cystitis, male infertility (oligospermia), metabolic alkalosis, peripheral vascular disease, surgery preparation and recovery, trauma, wound healing enhancement.

Deficiency Symptoms

Arginine deficiency is uncommon and is usually related to overall protein malnutrition (especially protein deficiency), compromised health status or elevated physiological stress (e.g., burns, injury, infection), excessive ammonia production, or enzyme deficiency. Primary symptoms include rash, hair loss, poor wound healing, constipation, fatty liver, and cirrhosis.

Dietary Sources

The best dietary sources of arginine are meat (especially lamb), peanuts, soybeans, hazelnuts, shrimp, eggs, and milk products. Other foods containing significant mounts of arginine include: almonds, cashews, Brazil nuts, filberts, pecans, sesame and sunflower seeds, walnuts, raisins, coconut, gelatin, chicken, chocolate, brown rice, barley, buckwheat, corn, and oats.

Lysine competes with arginine for absorption, so a diet low in lysine may enhance the effects of arginine intake.

Dosage Forms Available

Capsules, powder, or tablets, containing a salt of L-arginine, such as L-arginine hydrochloride, or arginine glutamate; the free base amino acid is also sometimes used, although it is more problematic to use in a capsule or tablet because it is very hygroscopic.

- Well absorbed orally, with time to peak serum concentration approximately 2 hours.
- Best taken away from meals, in divided doses, throughout day.
- Intravenously administered for pituitary function test.

Dosage Range

Adult

Dietary: Optimal levels of intake have not been established.
Supplemental/Maintenance: 1.5 to 6.0 grams per day, usually 2 to 3 g/day; best in divided doses because absorption of doses greater than 3 g is usually poor. Arginine can be synthesized endogenously, and supplementation is usually not necessary for most individuals.
Pharmacological/Therapeutic: Researchers and practitioners of nutritional therapeutics have used a wide range of dosages, from 2 to 30 g daily, with 6 g daily being representative for most conditions. For example, 6 to 15 g daily has been used in CHF treatment. Long-term use is usually not advisable.

Pediatric (=<18 Years)

Dietary: Optimal levels of intake have not been established.
Supplemental/Maintenance: Usually not administered as a nutritional supplement to children.
Pharmacological/Therapeutic: Usually not administered therapeutically to children, except possibly in relation to burns, injuries, or surgery; in such cases, dosage levels would be proportional to typical adult doses by weight.

Laboratory Values

Research laboratory methods for measuring NOS activity are available, but they are not used clinically to any significant degree. Serum and urine amino acid profiles are available, but not likely to be clinically relevant to the status of arginine-derived NO production capability, because more factors are involved than simply the amount of arginine present in tissues and body fluids. Therefore, effects of arginine supplementation are best judged clinically. Various measures of circulatory and endothelial function are most likely to show changes if supplemental arginine enhances NOS activity, as well as blood pressure, erectile function, and exercise tolerance.

SAFETY PROFILE

Overview

Dosage levels of 1 to 6 g per day generally are well tolerated by healthy adults. Adverse effects are estimated to occur in 1% to 10% of patients administered arginine, with more severe reactions associated with intravenous (IV) administration.

Nutrient Adverse Effects

General Adverse Effects

Minor gastrointestinal (GI) distress is occasionally associated with supplemental intake; headache also may occur. Excessive doses of arginine (>40 g/day) may cause diarrhea, most likely as a result of poor absorption at higher dosage levels. Rapid IV infusion may produce flushing.

Despite numerous studies demonstrating the immune-enhancing activity of arginine, including research with breast cancer, some researchers have suggested that high doses of arginine can increase the growth of cancer cells in humans.[1-4] Clinicians with experience in integrative oncology have observed that amino acids, particularly arginine, can have opposite effects at different stages in the disease process, for tissues at different sites, and for different individuals. Further research into such aspects of nutritional therapeutics within cancer prevention and treatment are warranted to delineate

such patterns and determine their implications in developing therapeutic strategies. However, pending such studies, the influence of arginine on growth of cancers can generally be qualified as unpredictable.

Adverse Effects Among Specific Populations

Individuals with a history of gastritis, reflux esophagitis, or peptic ulcer disease may experience exacerbations with arginine administration, possibly from stimulation of gastrin. However, the evidence for such concern is mixed.

Hyperphosphatemia can be induced by arginine in patients with severe hepatic disease and kidney problems. The maximum safe dosage levels for arginine administration in individuals with compromised hepatic function have not been established.

Pregnancy and Nursing

Data on long-term safety for arginine administration in pregnant or lactating women are lacking, and maximum safe dosage levels have not been established.

Infants and Children

Data on long-term safety for arginine administration in infants and children are lacking, and maximum safe dosage levels have not been established.

Contraindications

Administration of L-arginine after acute myocardial infarction (MI) may lead to worsened clinical outcomes or death, particularly in older patients with diffuse atherosclerosis, and should be avoided except under the direct supervision of a physician trained and experienced in such interventions.[5] As a possible explanation for these results, it has been hypothesized that L-arginine may only help to alleviate vascular stiffness in patients with preexisting L-arginine deficiency. Continued research is warranted to clarify the role of L-arginine in cardiovascular health.

Avoidance of arginine supplementation by individuals with active or past herpes simplex virus (HSV) infections has often been asserted based on the theory that elevated arginine levels might stimulate viral replication or provoke an outbreak, especially in the context of low lysine levels. Although supported by broad anecdotal reports and older in vitro data,[6] evidence from clinical trials is lacking to confirm elevated susceptibility and validate this contraindication. Nevertheless, caution is warranted. If herpetic reactivations consistently occur shortly after initiating arginine administration or otherwise increasing intake, clinical anecdotes have suggested that a therapeutic trial of coadministration with equal amounts of L-lysine may be useful. Currently, no clinical evidence indicates whether or not L-lysine coadministration may interfere with L-arginine's bioavailability, based on the known competition between the two amino acids for intestinal absorption.

Arginine administration is generally contraindicated in individuals with hepatic or renal failure, except when clinically appropriate and then only under direct medical supervision.[7]

Individuals with a known history of hypersensitivity to arginine generally need to avoid supplemental intake.

Precautions and Warnings

Arginine administration, at usual dosage levels, is generally considered safe in individuals with stable type 2 diabetes mellitus. However, regular monitoring of blood glucose levels is appropriate in diabetic individuals supplementing with arginine because of possible effects on insulin and glucagon.[6]

INTERACTIONS REVIEW

Strategic Considerations

Despite positive findings from a range of disparate studies, scientific research on the therapeutic use of arginine has not matured; evidence of interactions involving arginine, based on well-designed clinical trials and documented case reports, is uneven and often absent. In many cases, well-known pharmacological principles enable us to predict many probable patterns of interaction, but the body of evidence articulating mechanisms, actions, and efficacy has not yet produced a consistent set of clinically applicable knowledge and related practices. Medical conditions and pharmaceutical agents that deplete or impair arginine status inherently influence relationships between NO and arginase and their interdependent levels and functions and consequently affect cardiac, muscular, and respiratory tissues and processes of growth, inflammation, and expansion/contraction. Interactions involving arginine are primarily characterized by their beneficial effect in supporting the therapeutic strategy and reducing drug adverse effects; such action inherently invokes the occasional bimodal interaction that carries potential for adverse or supportive character largely dependent on communication, observation, and responsive clinical management. Thus, for example, drugs that reduce arginase activity would theoretically increase arginine's availability to be converted to NO. Further research into this apparent bimodal activity of NO, and arginine, is warranted because some aspects of current knowledge suggest that excess NO levels might be involved in chronic inflammatory disorders. Any resulting evidence of peroxynitrate/nitrite formation from NO in situations of increased oxidative stress in the context of inadequate antioxidant reserves would suggest that clinicians give further attention to antioxidant reserves when administering arginine.

In some respects, arginine has already established a role for itself within the inpatient clinical setting, more so than in conventional outpatient care. Within critical care guidelines, arginine hydrochloride is considered a fourth-line treatment for uncompensated metabolic alkalosis after sodium chloride, potassium chloride, and ammonium chloride supplementation has been optimized. The immunomodulatory actions of arginine in nourishing hospitalized patients represent an area of continued research and significant potential benefit. Research on ***immunonutrition*** using arginine as part of parenteral formulas in combination with other nutrients has focused on mucosal barrier function, cellular defense, and local or systemic inflammation; results have been promising but mixed.

Within nutritional pharmacology and integrative therapeutic strategies, arginine is primarily used as a component of multifactorial interventions to promote detoxification (especially excretion of ammonia), stimulate immune function and modulate inflammation, aid wound healing, enhance healthy function of cardiac and vascular tissue, and promote secretion of several hormones, including glucagon, insulin, and GH. Thus, the emerging concept of immunonutrition as a proactive component of an integrative therapeutic strategy represents a convergence of conventional practice and nutritive therapies, with further research inevitable.

NUTRIENT-DRUG INTERACTIONS

ANTIHYPERTENSIVE MEDICATIONS

Angiotensin-Converting Enzyme (ACE) Inhibitors

Benazepril (Lotensin), combination drug: benazepril and amlodipine (Lotrel); captopril (Capoten); captopril and hydrochlorothiazide (Acezide, Capto-Co, Captozide, Co-Zidocapt); cilazapril (Inhibace), enalapril (Vasotec); combination drugs: enalapril and felodipine (Lexxel); enalapril and hydrochlorothiazide (Vaseretic); fosinopril (Monopril), lisinopril (Prinivil, Zestril), lisinopril and hydrochlorothiazide (Prinzide, Zestoretic); moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), ramipril (Altace) trandolapril (Mavik).

Potassium-Sparing Diuretics

Amiloride (Midamor), spironolactone (Aldactone), triamterene (Dyrenium).

Combination drugs: amiloride and hydrochlorothiazide (Moduretic), spironolactone and hydrochlorothiazide (Ald-actazide), triamterene and hydrochlorothiazide (Dyazide, Maxzide).

Interaction Type and Significance

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **4. Plausible**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Hyperkalemia and hypotension are uncommon but potentially serious adverse effects associated with angiotensin-converting-enzyme (ACE) inhibitors, as a class (especially when combined with a potassium sparing diuretic or aldosterone antagonist), as well as with other antihypertensive agents.[8-10] Arginine administration can elevate potassium levels and produce arterial dilation. Intravenous arginine infusions can be used to treat metabolic alkalosis (in patients unresponsive to sodium chloride or potassium chloride supplementation) and are particularly known to induce hyperkalemia; they are also employed in laboratory testing for GH deficiency. Insulin and GH are also both responsive to arginine intake. Concomitant administration of arginine and antihypertensive medications (e.g., ACE inhibitor, potassium-sparing diuretic) could result in an additive effect on potassium levels, phosphorus levels, vascular dilation, and blood pressure lowering.

Research

Key factors that contribute to the potential interaction between arginine and ACE inhibitors have been the subject of human research, but comprehensive research is still in preliminary stages. Coadministration of arginine with ACE inhibitors alone or with other antihypertensive agents could potentially enhance the therapeutic effect on hypertension. However, unsupervised concomitant use of ACE inhibitors and arginine could result in excessive arginine levels, which would primarily manifest as excessive arterial dilation and inadvertent hypotension, through an additive effect.

In a small clinical trial involving 19 normal subjects, Massara et al.[11] noted that plasma phosphorus fell significantly; in 11 of 12 subjects, plasma potassium levels rose significantly after a 0.5 g/kg arginine infusion. In another small, controlled trial, Pezza et al.[12] found that hypertensive patients refractory to enalapril and hydrochlorothiazide responded favorably when arginine (2 g three times daily orally) was coadministered. In a double-blind trial involving 35 patients with essential hypertension, Abbott and Bakris[13] observed improved arterial dilation in subjects who received 6 g L-arginine in a one-time dose versus placebo (although it not did not change blood pressure immediately). No clinical trial or formal interactions research has been performed specifically investigating the effects of concomitant arginine and ACE inhibitor administration.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing antihypertensive medications such as ACE inhibitors or potassium-sparing diuretics are advised to ask patients about possible arginine supplementation and, if deemed clinically appropriate, closely supervise and regularly monitor such individuals for possible interactions between these agents. The nature of the possible interaction is variable, potentially beneficial or adverse, and still largely uncertain; effects in any given individual are likely to be influenced by such factors as dosage, timing, general health status, comorbid conditions, and pharmacogenomic variability. Physicians providing IV arginine should exercise special caution in administering such diagnostic procedures or therapeutic interventions to individuals who are also taking ACE inhibitors.

Caution and careful management are warranted in any patient supplementing with arginine while taking antihypertensive medications. Well-designed clinical trials comparing the effects of concomitant administration of antihypertensive medications and arginine are warranted to further determine arginine's ability to complement conventional antihypertensive therapy, determine parameters of appropriate usage and contraindications, and elucidate therapeutic protocols for effective integrative therapeutics.

Cyclosporine

Cyclosporine (Ciclosporin; cyclosporin A, CsA; Neoral, Sandimmune, SangCya).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **4. Plausible**

Evidence Base: ▽ **Mixed**

Effect and Mechanism of Action

L-Arginine is the substrate for nitric oxide (NO) synthesis. A diminished role of the NO/cyclic guanosine monophosphate (cGMP)–mediated vasodilator mechanism, particularly NO blockade, may be responsible for cyclosporine-induced vascular dysfunction. Nitric oxide can decrease cyclosporine nephrotoxicity; it can also have both effector (cytotoxic) and regulatory roles in immune function. L-Arginine is also the substrate for both nitric oxide synthase (NOS), which produces NO, and a component in the experimental NOS inhibitor, N-nitro-L-arginine-methyl ester (L-NAME); both substances have been shown to modify acute cyclosporin A (CsA)–induced intrarenal vasoconstriction.

Research

Arginine has many beneficial effects on the kidneys and may be beneficial in many forms of renal disease, including hypertension and ureteral obstructive nephropathy. A series of studies using a rat model indicate that oral administration of L-arginine can

prevent chronic cyclosporine nephrotoxicity through effects on NO metabolites and cGMP.[14-16] Initially, Andoh et al.[14] found that "chronic CsA nephrotoxicity can be aggravated by NO blockade and ameliorated by NO enhancement." Later, Lee et al.[16] conducted in vitro experiments using tissue isolated from the thoracic aorta of normal rats and those acutely treated with CsA to investigate vascular relaxation response to acetylcholine and tissue levels of NO metabolites and cGMP. They found that acute treatment with CsA in vitro greatly attenuated the vasorelaxation response to acetylcholine and that such response was completely restored by L-arginine. The vascular accumulation of NO metabolites in response to acetylcholine was decreased significantly by CsA, but coadministration of L-arginine prevented this effect. While CsA decreased cGMP accumulation in response to acetylcholine (and sodium nitroprusside), acetylcholine-stimulated cGMP generation was restored, although not completely, by L-arginine, but it did not affect sodium nitroprusside–stimulated cGMP generation. After chronic CsA treatment in the whole animal, the vasorelaxation response to acetylcholine was decreased significantly, along with tissue levels of NO metabolites; administration of L-arginine preserved this effect. The authors concluded: "CsA causes an L-arginine-sensitive vascular dysfunction which is associated with impaired generation of NO and cGMP."[16] Other research with animals indicates that arginine may inhibit tumor growth by activating macrophage cytotoxic effects.[17]

Zhang et al.[18] conducted a randomized, double-blind clinical trial involving 11 young renal allograft recipients, age 11 to 22 years, with chronic renal transplant dysfunction treated with CsA. The subjects were randomly assigned to a 6-week treatment period with placebo, followed by two subsequent 6-week periods with L-arginine supplementation (0.1 g/kg/day) or 6-week treatment with L-arginine, followed by two subsequent 6-week periods with placebo. At the end of each treatment period, 24-hour blood pressure readings were taken, and glomerular filtration rate (GFR), renal perfusion function (RPF; PAH clearance), and urinary excretion of protein, albumin, nitrate, cGMP, and urea were evaluated. These researchers found that subjects receiving arginine did not demonstrate significant changes in GFR, RPF, proteinuria/albuminuria, mean systolic/diastolic blood pressure, compared with placebo. These researchers concluded that arginine administration "did not improve renal function and did not decrease proteinuria in CsA-treated renal allograft recipients with chronic transplant dysfunction possibly because of inhibition of NO-cGMP forming mechanism."[18] Given the negative results of this small clinical trial, with the suggestive preclinical data, clinicians might consider the question of how a trial might be designed with a stronger opportunity for a positive outcome. Higher doses, longer term, starting arginine vs. placebo concurrent with CsA, or other design variants might enable investigators to determine if CsA nephropathy can be prevented, if correction is not obtainable. Arginine may also increase oxidative stress by forming peroxynitrite radicals (NO reacting with superoxide radicals), so some measure of oxidative stress and correction with either dietary or supplemental antioxidants may be needed to demonstrate benefit.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The body of research on arginine can reasonably be interpreted as supporting the general hypothesis that arginine may provide a salutary effect to renal function, particularly in individuals whose kidneys are in a compromised state. However, the mixed character and preliminary state of the available research data suggest that sufficient evidence is lacking to support coadministration of L-arginine as likely to offer significant definite benefit to patients undergoing cyclosporine therapy. Well-designed clinical trials comparing different dosage levels of arginine and pretreatment versus coadministration are warranted to further determine arginine's ability to mitigate adverse effects of CsA therapy and elucidate therapeutic protocols for effective integrative therapeutics.

Sildenafil and Related Phosphodiesterase-5 Inhibitors

Evidence: Sildenafil (Viagra).
Extrapolated, based on similar properties: Tadalafil (Cialis), vardenafil (Levitra).

Interaction Type and Significance
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
3. Possible

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action

The vasodilation necessary to an erection depends on NO.[19] The vasodilatory effect of arginine, as an enhancer of NO production, is broadly accepted. Sildenafil is generally considered to require the presence of NO for its effectiveness.[20,21] Other phosphodiesterase-5 (PDE-5) inhibitors, such as tadalafil and vardenafil, have exactly the same mechanism of action, varying only in pharmacokinetic parameters.

Research

Research into the therapeutic value of arginine in the treatment of men with erectile dysfunction (ED) is in preliminary stages, but the findings thus far support the hypothesis that enhancement of NO status can be efficacious, especially in men with NO deficiency or metabolic dysfunction.

In a small preliminary trial, Zorgniotti and Lizza[22] found that 6 of 15 men with ED demonstrated improvement after taking arginine, 2800 mg/day, for 2 weeks, versus no reported improvement with placebo. Subsequently, in a prospective randomized, double-blind, placebo-controlled trial, Chen et al.[23] administered arginine, 5 g/day, or placebo to 50 men with ED for 6 weeks. Plasma and urine nitrite and nitrate (designated NOx), both stable metabolites of NO, were determined at the end of the placebo run-in period and after 3 and 6 weeks. Nine of 29 (31%) patients taking L-arginine, as well as 2 of 17 controls, reported a significant subjective improvement in sexual function. However, plasma and urine NOx levels, which served as objective variables, remained unchanged. All nine patients who had subjectively improved sexual performance after being treated with L-arginine had initially demonstrated low urinary NOx, levels of which had doubled at the end of the study. Thus, these researchers concluded that arginine was particularly effective at providing significant subjective improvement in sexual function in men with organic ED who had abnormal NO metabolism, particularly decreased NOx excretion or production.

In a randomized trial involving 116 men who had undergone non-nerve-sparing radical pelvic surgery (64 prostatectomies and 52 cystectomies), Mantovani et al.[19] compared erectile function in those treated with sildenafil alone versus those administered both sildenafil and L-arginine. An initial 50-mg dose was inefficient in both groups (using Buckling test for evaluation), but 100-mg doses gave significant results

(Buckling test >500) in both groups, especially those receiving the combined treatment.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing sildenafil for the treatment of ED are advised to discuss with patients the potential benefits of concomitant arginine therapy. Based on preliminary evidence, a beneficial interaction between sildenafil and supplemental arginine appears to be possible as a result of the additive effects of the actions of these substances on NO function, especially in individuals with abnormal NO metabolism. Such simultaneous administration could alter the effects and the dosage levels and timing appropriate to safe and effective therapeutic application of sildenafil. Of note, the effects of arginine on NO production are best produced by chronic administration, whereas the effects of sildenafil and the other PDE-5 inhibitors, occur with acute (i.e., on-demand) administration. Suggested arginine dosage levels have not been definitively established, although clinical experience suggests that 6 g daily is a reasonable target. Thus, close supervision and regular monitoring are appropriate, even though evidence is lacking to suggest a significant risk of adverse reactions. Well-designed clinical trials investigating the effects of arginine alone and together with PDE-5 inhibitors are warranted to further determine arginine's ability to complement conventional therapy, determine parameters of appropriate usage and possible contraindications, determine effective dosage levels, and elucidate therapeutic protocols for effective integrative therapeutics.

Theophylline/Aminophylline

Theophylline/aminophylline (Phyllocontin, Slo-Bid, Slo-Phyllin, Theo-24, Theo-Bid, Theocron, Theo-Dur, Theolair, Truphylline, Uni-Dur, Uniphyl); combination drug: ephedrine, guaifenesin, and theophylline (Primatene Dual Action).

Interaction Type and Significance

⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

Probability:
4. Plausible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Nitric oxide deficiency appears to play a major role in inducing airway hyperreactivity and other aspects of asthma pathogenesis. In particular, a relative deficiency of NO caused by increased arginase activity and altered L-arginine homeostasis is a major factor in the pathology of asthma.[24] Based on research of arginine metabolism and caffeine action, the therapeutic action of theophylline (aminophylline) may be attributable, at least in part, to their effect in increasing cellular levels of cyclic adenosine monophosphate (cAMP) and thereby depressing arginase activity.[25] Drugs that reduce arginase activity would theoretically increase arginine's availability to be converted to NO. Administration of arginine in the context of methylxanthine therapy could create a beneficial additive or synergistic effect against pathophysiological components of asthma by enhancing NO levels.

Research

These bronchodilator drugs are primarily used in the treatment of asthma, for which arginine's central role is becoming increasingly clear within the scientific literature and medical research. Nitric oxide is a critical regulator of airway physiology, including airway and vascular smooth muscle tone.[26] The NOS and arginase pathways interfere with each other through substrate competition. A review of recent research indicates that a deficiency of beneficial, bronchodilating, constitutive NOS (cNOS)–derived NO is important in allergen-induced airway hyperresponsiveness, and that increased arginase activity and decreased cellular uptake of L-arginine appear to play a key role.[24] Interpreting the findings of Zimmermann et al.,[27] based on a mouse model, Vercelli[28] showed that "NO inhibition resulted from substrate competition," because expression of arginase, but not NOS, was altered in the lungs of the allergen-challenged mice. Meurs et al.[29] found that increased arginase activity underlies allergen-induced deficiency of cNOS-derived NO and airway hyperresponsiveness. Arginase expression appears to be controlled by Th2 cytokines, central mediators of allergic asthma.[30] During allergic inflammation, increased IL-4 and/or IL-13 expression results in increased expression of arginase and amplification of the arginase-dependent pathway, with concomitant suppression of NO generation.[28] In particular, "while these enzymes are constitutively expressed, NOS-2 is an inducible enzyme independent of calcium and highly induced in inflammatory diseases such as allergic asthma, where NO may act beneficial or deleterious depending on the site ... and amount of generation."[26] The emerging connections between the NO pathway, inflammatory response, and collagen generation "make arginine metabolism a rising star in the asthma firmament."[28]

Wechsler et al.[31] demonstrated an increased NO concentration in exhaled air in patients with asthma and observed an association with the asthmatic phenotype, in particular, NOS-1 genotype. Morris et al.[32] measured amino acid levels, arginase activity, and NO metabolites in the blood of asthmatic patients, as well as NO in exhaled breath. They found that "although levels of virtually all amino acids were reduced, asthmatic patients exhibited a striking reduction in plasma arginine levels compared to non-asthmatic normal controls." These researchers concluded: "High arginase activity in asthmatic patients may contribute to low circulating arginine levels, thereby limiting arginine bioavailability and creating a nitric oxide deficiency that induces hyperreactive airways."

The compiled findings could be interpreted to support the hypothesis that arginine could serve as a therapeutically efficacious component of a comprehensive strategy for the treatment of individuals with asthma, or at least some subpopulation, whether refractory to conventional care or defined by one or more genomic factors. Further, given the known and emerging knowledge of the mechanisms of action exerted by methylxanthines, a beneficial interaction appears pharmacologically plausible from concomitant administration of arginine with these agents.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing theophylline (or other methylxanthines) might consider discussing with patients the possible benefits of arginine administration, if deemed clinically appropriate. The nature of the possible interaction is variable, with possibly beneficial but also potential (although as yet unknown) adverse effects, in any given individual and likely to be influenced by such factors as dosage, timing, general health status, comorbid conditions, and pharmacogenomic variability. Close supervision and regular monitoring of such individuals for therapeutic response and potential adverse interactions are warranted.

Asthma is a disease of inherent complexity and variability that remains a major medical and scientific challenge despite intense research efforts and a growing number of affected individuals.

Although inhaled corticosteroids and beta-2-agonist bronchodilators have become the mainstay of asthma therapy, a complete understanding of the pathogenetic mechanisms of the disease, as well as diverse and difficult to define factors of individual variability in susceptibility, presentation, and exacerbation, continues to elude researchers. Caution and careful management are warranted when modifying the therapeutic intervention in any patient with asthma, especially those taking bronchodilators, whether inhaled or systemic. Well-designed clinical trials investigating the effects of arginine alone and together with theophylline (or other methylxanthines) are warranted to further determine arginine's ability to complement conventional bronchodilator therapy, determine parameters of appropriate usage and contraindications, and elucidate therapeutic protocols for effective integrative therapeutics.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Estrogen-Progestin Combinations

Oral Contraceptives: Monophasic, Biphasic, and Triphasic Estrogen Preparations (Synthetic Estrogen and Progesterone Analogs)

Hormone Replacement Therapy, Estrogen-Containing and Synthetic Estrogen and Progesterone Analog Medications

The concomitant use of an estrogen-progestin combination and an arginine preparation might theoretically result in increased toxicity effects because of resultant effects on GH response and glucagon and insulin effects. Although this interaction appears plausible, there is a lack of evidence from clinical trials and well-documented case reports characterizing such an interaction, defining its frequency and context of occurrence, or establishing its clinical implications.

Nitrates

Amyl nitrate, isosorbide dinitrate (ISDN, Isordil, Sorbitrate); combination drug: hydralazine and isosorbide dinitrate (BiDil); isosorbide mononitrate (Imdur, ISMN, ISMO, Isotrate, Monoket).

Members of the nitrate family of drugs are used to prevent angina. Human research has shown that arginine, as an NO precursor, also is potentially beneficial for individuals with angina or other cardiovascular conditions. An interaction between nitrate medications and arginine could potentially result from the additive effects of the similar actions of these substances if taken concomitantly. Such simultaneous administration could alter the effects and the dosage levels and timing appropriate to safe and effective therapeutic application of these agents.[33] Evidence from clinical trials or documented case reports is lacking at this time to confirm this theoretically possible interaction or characterize its frequency, context, or severity.

Pentoxifylline

Pentoxifylline (Pentoxil, Trenta).

Based on research of arginine metabolism and caffeine action, the therapeutic action of pentoxifylline may be attributable, at least in part, to the shared effect of methylxanthines in increasing cellular levels of cAMP and thus depressing arginase activity and increasing arginine's availability for conversion to NO.[25] Evidence from clinical trials or documented case reports is lacking at this time to confirm this theoretically possible interaction or characterize its frequency, context, or severity. Pentoxifylline's documented, though modest, enhancement of compromised circulation would theoretically synergize with arginine's ability to enhance endothelial function and vasodilation by optimizing NO production. Well-designed clinical trials to explore such possible synergy would seem indicated.

NUTRIENT-NUTRIENT INTERACTIONS

Lysine

Within the world of nutritional anecdotes, the antagonistic relationship between L-lysine and L-arginine has taken on almost self-evident status, particularly within the context of preventing herpes simplex by administering lysine and reducing arginine intake. However, although the evidence supporting such conclusions is emerging, it remains inconclusive.

Arginine and lysine compete for absorption into cells, so increased intake of either amino acid can decrease levels of the other. Consequently, a diet low in lysine can enhance effects of arginine supplementation because lysine competes with arginine for absorption. Furthermore, increased arginine intake is reputed to enhance arginine status, together with the benefits and risks attendant to such an environment. This competitive relationship appears to be founded on reasonable pharmacological principles.

Anecdotal reports based on consumption of foods with a high arginine/lysine ratios (e.g., nuts, peanuts, chocolate) and in vitro research dating back to 1964 indicate that HSV has a high requirement for arginine and lysine inhibits viral replication.[6] Findings from several clinical trials of varying size and design have generally supported the hypothesis that lysine intake reduces the recurrence rate of HSV infections.[34-38]

Although the available evidence is strongly suggestive rather than conclusive, conservative practice warrants approaching arginine and lysine as metabolic competitors and therefore requiring that diet and supplemental intake be adjusted in accordance with clinical objectives. The immune-enhancing functions of arginine are well known, but it appears judicious to advise decreasing arginine intake and increasing lysine intake with susceptible individuals, to prevent or resolve herpes simplex outbreaks. Further research with large, well-designed clinical trials is warranted to advance and clarify the metabolic relationship between these two amino acids, define factors of individual variability in response patterns and disease susceptibilities, and develop balanced and comprehensive guidelines for evidence-based clinical application of these key nutrients.

Omega-3 Fatty Acids (Fish Oils)

In a 6-month, prospective, randomized, double-blind controlled study involving 64 HIV-infected outpatients (with CD4 lymphocyte count $\geq 100 \times 10^6$/L), Pichard et al.[39] found that the addition of arginine and omega-3 fatty acids did not improve immunological parameters, compared with a group receiving only the base multinutrient oral supplement; body weight increased in both groups. The synergy between omega-3 fatty acids and arginine in supporting wound healing and tissue regeneration warrants further research and development of evidence-based clinical guidelines.

See also Parenteral and Enteral Nutritional Formulations.

Ornithine

Interest in the potentially beneficial synergy between arginine and ornithine largely derives from knowledge of arginine's function as a precursor of ornithine and their respective roles

in GH secretion. Approximately 50% of arginine intake is rapidly converted to ornithine, primarily through the action of arginase. Ornithine can subsequently be metabolized to glutamate and proline, or into the polyamine pathway, under the action of ornithine decarboxylase.[40]

Coadministration of arginine and ornithine, often with other nutrients, has been suggested as a means of enhancing GH levels and thereby increasing development of muscle tissue and lean body mass, increasing gains in strength, and decreasing proportional body fat, primarily within the context of athletic training and body building.

Elam[41] reported that coadministration of arginine and ornithine (500 mg each twice daily, five times weekly) in a controlled clinical trial involving adult males, in conjunction with resistance exercise, produced a significant decrease in body fat. Subsequently, in a double-blinded clinical trial framed around a 5-week progressive strength-training program, Elam observed that a arginine-ornithine combination (1 g each, orally, five times weekly) scored significantly higher gains in total strength and enhancement of lean body mass compared to controls administered vitamin C and calcium as placebo. Elam et al.[42] also noted that arginine and ornithine enhanced recovery from chronic physiological stress by quelling tissue breakdown, as evidenced by lower urinary hydroxyproline levels.

However, Marcell et al.[43] found that acute arginine administration (5 g orally 30 minutes before exercise) did not stimulate basal or augment exercise-induced GH secretion in either young or old adults and may actually have impaired GH secretion in young adults.

Further research comparing timing, duration, and dosage levels of combined supplementation with arginine and ornithine through clinical trials of adequate size and appropriate design is warranted to elucidate the relationship of these nutrients in building lean body mass, particularly muscle tissue, and facilitating breakdown of adipose tissue.

Parenteral and Enteral Nutrition Formulations Containing Antioxidants, Fatty Acids, and Other Nutrients

Arginine is often used with nutrients as part of multi-ingredient immunonutrition-parenteral formulas administered to patients who are recovering from injury, burns, or surgery or otherwise critically ill. Three meta-analyses found that immunonutrition results in notable reductions in infection rate and length of hospital stay, with greater benefit observed in surgical than critically ill patients. However, there was an overall lack of significant impact on outcomes, particularly mortality, and at least one study indicated significant risk of increased mortality in critically ill patients receiving immunonutrition, especially when sepsis was involved.[44-49] "A biphasic response with an early hyperinflammatory response followed by an excessive compensatory response associated with immunosuppression" is seen in many critically ill patients.[49] Several clinical trials have reported positive outcomes (as indicated by measures of immune function) in oncology and trauma recovery patients administered formulations containing arginine, glutamine, omega-3 fatty acids, RNA or nucleotides, and other nutrients, typically in the form of enriched enteral diets.[50-54]

In a prospective, multicenter, single-blind, randomized trial, Caparros et al.[55] investigated the effect on nosocomial infections and outcome of early enteral nutrition in 220 critically ill intensive care unit (ICU) patients with a high-protein diet enriched with arginine, fiber, and antioxidants, compared with a standard high-protein diet. These researchers found that critically ill patients fed a high-protein diet enriched with arginine, fiber, and antioxidants had a significantly lower catheter-related sepsis rate than patients fed a standard high-protein diet. Further, although there were no differences in mortality or ICU and hospital length of stay between the two groups, the patients fed the study diet for more than 2 days showed a trend toward decreased mortality.

The preliminary nature and sometimes contradictory findings of studies thus far conducted suggest that different nutrient formulations may be appropriate for varying patient populations. Continued research into these integrative approaches to nutritional support within inpatient care settings, in general, and critical care, in particular, through large, well-designed clinical trials, is clearly warranted.

HERB-NUTRIENT INTERACTIONS

Yohimbe

Yohimbe *(Pausinyitalia yohimbe; Corynanthe yohimbe (Corynanthejohimbe)*.

The major identified alkaloid in yohimbe is *yohimbine*, an alkaloid that blocks alpha-adrenergic outflow, thereby increasing parasympathetic tone. This can promote erectile function, as well as have blood pressure–lowering effects. Purified yohimbine is a prescription drug in the United States, but it is also found in herbal preparations at lower doses.

In a double-blind, placebo-controlled, three-way crossover, randomized clinical trial involving 45 men with ED, Lebret et al.[56] compared the efficacy and safety of the combination of L-arginine glutamate (6 g) and yohimbine hydrochloride (6 mg) with that of yohimbine hydrochloride (6 mg) alone and that of placebo, administered orally, 1 to 2 hours before intended sexual intercourse. Based on the findings from this pilot study, these researchers concluded that "the on-demand oral administration of the L-arginine glutamate (6 g) and yohimbine (6 mg) combination is effective in improving erectile function in patients with mild to moderate erectile dysfunction," as measured by Erectile Function Domain scores and patients' assessment of efficacy.

Well-designed clinical trials investigating the combined effects of arginine and yohimbe derivatives are warranted to further determine safety and efficacy, determine parameters of appropriate usage and possible contraindications, determine effective dosage levels, and elucidate therapeutic protocols for effective integrative therapeutics.

The 56 citations for this monograph, as well as additional reference literature, are located under Arginine on the CD at the back of the book.

Carnitine

Nutrient Name: Carnitine.
Synonyms: L-Carnitine, levocarnitine; vitamin BT.
Forms: Acetyl-L-carnitine (ALC), L-acetylcarnatine (LAC); propionyl-L-carnitine (PLC), L-propionylcarnitine (LPC).
Related Substance: D-Carnitine (synthetic isomer).

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Allopurinol ⊕⊕	Carnitine deficiency is characteristic of Duchenne muscular dystrophy, particularly affecting mitochondrial metabolism and muscle tissue. Allopurinol restores carnitine levels in such individuals. Coadministration of carnitine could theoretically enhance this intervention.	Treat with allopurinol; consider carnitine coadministration.
Doxorubicin Anthracycline chemotherapy ≈≈/☼	Cardiotoxicity is a common and irreversible adverse effect of doxorubicin therapy, sometimes acute, often chronic or delayed. Coadministration of carnitine before, during, and after chemotherapy can prevent and reduce cardiomyopathy and other toxic effects, partly because of its role in supporting fatty acid oxidation and cardiac function. Nutrient support is nontoxic and unlikely to interfere with doxorubicin's therapeutic activity.	Coadminister, closely monitor cardiac and renal function. Consider liposomal forms.
Isotretinoin Retinoids ☼	Carnitine can prevent or reduce adverse effects of isotretinoin, particularly myalgia and hypertriglyceridemia, partly because of its role in supporting fatty acid oxidation, mitochondrial metabolism, and hepatic detoxification. Nutrient support is nontoxic and unlikely to interfere with therapeutic activity of retinoids.	Coordinated use with separated administration; closely monitor.
Levothyroxine Thyroid hormones ✗✗/⊕✗/☼	Carnitine inhibits thyroid hormone nuclear uptake and may partially block activity of thyroid hormone. Carnitine contraindicated in hypothyroidism (frank or subclinical) but valuable with hyperthyroidism, endogenous or iatrogenic.	Caution against carnitine supplementation in hypothyroid states. Administer with monitoring when thyroid hormone antagonist appropriate.
Nitroglycerin ⊕⊕/⊕✗/✗	Carnitine can support cardiac function and reduce ischemia and angina through its action on mitochondrial metabolism, fatty acid oxidation, and myocardial function. Coadministration of carnitine may reduce incidence and severity of angina and enable reduced nitroglycerin dosage. Theoretical risk of additive response.	Coadminister carnitine; monitor.
Pivampicillin, pivmecillinam Pivalate prodrugs ≈≈	Pivalate prodrugs cause carnitine depletion through urinary excretion of pivaloyl-carnitine. Depletion inherent but of minimal clinical significance in most individuals with short-term drug intake. Adverse effects can be acute and potentially significant in susceptible individuals (e.g., infants and children, carnitine deficient, AEDs), but adverse effects primarily associated with chronic or recurrent use. Carnitine support can prevent or reverse depletion and adverse sequelae.	Carnitine coadministration may be prudent but usually unnecessary.
Simvastatin HMG-CoA reductase inhibitors (statins) ⊕⊕/☼	Statin therapy is generally ineffective (and sometimes counterproductive) in reducing lipoprotein(a) and its atherogenic and prothrombotic effects. L-carnitine appears efficacious in lowering lipoprotein(a) levels, particularly in patients with type 2 diabetes. Several trials show therapeutic benefits from L-carnitine, particularly in combination with simvastatin, in treating this form of dyslipidemia. No adverse effects have been reported.	Coadminister L-carnitine within comprehensive program, including statin.
Valproic acid (VPA) Anticonvulsant medications ≈≈/☼/⊕	Anticonvulsant medications (AEDs), particularly VPA, deplete carnitine and can cause clinically significant deficiency with long-term use, especially in children and with polytherapy. Other factors in patient population, besides drug effect, may contribute to compromised carnitine status. Coadministration of carnitine can prevent or reverse adverse medication effects but may be unnecessary in many patients.	Coadminister carnitine; monitor.
Zidovudine (AZT) Reverse-transcriptase inhibitor (nucleoside) antiretroviral agents ◈≈≈/≈≈/☼/⊕	Carnitine deficiency is characteristic of HIV infection, notably affecting mitochondrial metabolism, fatty acid oxidation, and immune function. Carnitine can prevent or reduce adverse effects of AZT and related antiviral medications, particularly accumulation of lipid droplets within muscle fibers from poor utilization of long-chain fatty acids.	Coadminister carnitine; monitor.

AEDs, Antiepileptic drugs; *HIV*, human immunodeficiency virus.

NUTRIENT DESCRIPTION

Chemistry and Forms

Carnitine (3-hydroxy-4N-trimethylammoniumbutanoate) is a naturally occurring quaternary amine. Forms include acetyl-L-carnitine (ALC; L-acetylcarnitine, LAC) and propionyl-L-carnitine (PLC; L-propionylcarnitine, LPC).

Physiology and Function

Carnitine (levocarnitine, L-carnitine) is considered to be a nonessential amino acid, although in certain situations it is considered conditionally essential (e.g., dialysis patients, premature and very-low-birth-weight infants, coronary artery disease). The highest concentrations of carnitine are found in the

heart, muscles, liver, and kidney. The major biochemical function of carnitine is to act as a transmembrane carrier of long-chain fatty acids to the interior of mitochondria. It plays a major role in the utilization of fats in energy production at the mitochondrial level through the beta-oxidation of branched-chain amino acids and ketoacids. Carnitine also participates in transportation of acyl-coenzyme A (CoA) compounds. The activated long-chain fatty acyl-CoA esters in the cytosol are able to be transported to the mitochondrial matrix only by combining with carnitine. Beta-oxidation, the primary metabolic process by which fatty acids, branched-chain amino acids, and ketoacids (as acyl-coA esters) are used as fuel for cellular energy, occurs in the mitochondria. Thus, carnitine functions as an important physiological mediator of fatty acid and protein metabolism. Carnitine also enables hepatic detoxification and excretion of chemicals, including drugs, and improves glucose disposal and may reduce insulin resistance. Carnitine is instrumental in the production and release of acetylcholine.

Carnitine from dietary sources is rapidly absorbed from the intestinal tract by both passive and active transport. Although it exhibits vitamin-like properties, carnitine is a small amino acid derivative that can be synthesized de novo in the liver, brain, and kidneys using lysine and methionine in a process requiring vitamins C, B_6, and niacin. Exogenous intake may be necessary during periods of increased demand or increased loss. Acetyl-L-carnitine (ALC), the acetylated derivative of L-carnitine, is particularly localized in muscles, brain, and testicles.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Carnitine's central role in muscle function and fat metabolism has drawn the attention of clinicians and researchers to clinical applications related to these roles. Carnitine is proposed for increasing endurance and improving cardiac performance based on its known action of enhancing the efficiency of energy production in muscle tissue in general and the myocardium in particular. Human research has focused on therapeutic application of carnitine, especially as propionyl-L-carnitine (PLC), in the treatment of angina, myocardial insufficiency, peripheral claudication, and other conditions related to arterial insufficiency. Cardiac L-carnitine content, essential for mitochondrial fatty acid transport and adenosine triphosphate (ATP)–diphosphate (ADP) exchange, decreases during ischemia. Furthermore, acetyl-L-carnitine (ALC) has been administered for slowing, and even partially reversing, nerve and brain deterioration associated with the aging process. Thus, the primary potential clinical uses for carnitine include claudication, Alzheimer's disease, myocardial insufficiency, and renal dialysis. Hyperlipidemia, male infertility, athletic performance, and weight loss have also been the subjects of therapeutic claims and evolving investigations, although results have been more mixed.

During pregnancy, infancy, and breastfeeding (i.e., situations of high energy demands), the physiological need for L-carnitine can exceed the capacity for endogenous synthesis. Consequently, L-carnitine is often used as a supplement with breast milk or infant formula for low-birth-weight (LBW) infants (either preterm or full term).

Possible Uses

Attention deficit–hyperactivity disorder (ADHD), alcohol dependence, Alzheimer's disease, angina pectoris, anorexia nervosa, arrhythmias, atherosclerosis, athletic performance (enhancement), cardiac ischemia, cardiac surgery (recovery), cataracts, chronic fatigue syndrome, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF; propionyl-L-carnitine), dementia, depression in elderly (acetyl-L-carnitine), diabetes mellitus, diabetic cardiac autonomic neuropathy, erectile dysfunction, human immunodeficiency virus (HIV) infection, hyperactivity in fragile X syndrome, hypercholesterolemia, hyperthyroidism, hypertriglyceridemia, infertility (male), intermittent claudication, myocardial infarction, myocardial insufficiency (e.g., CHF or cardiomyopathy), Peyronie's disease, Raynaud's disease, renal dialysis, seizure disorders, weight loss.

Deficiency Symptoms

Carnitine deficiency is characterized by inadequate tissue levels, resulting in impaired tissue fatty acid oxidation. Other symptoms of a relative deficiency may include elevated blood lipids, abnormal liver function, chronic muscle weakness, reduced energy, impaired glucose control, cardiomyopathy, encephalopathy, and recurrent episodes of coma.[1]

Absolute carnitine deficiency is unlikely because of endogenous synthesis. Primary systemic carnitine deficiency is caused by a defect in the specific high-affinity carnitine transporter, which is expressed in most tissues and is responsible for bringing carnitine into the cytosol. This carnitine uptake defect is rare and is characterized by progressive infantile-onset carnitine-responsive cardiomyopathy, weakness, recurrent hypoglycemic hypoketotic encephalopathy, and failure to thrive.[2] Several inherited metabolic disorders, especially organic aciduras and disorders of beta-oxidation, can cause secondary carnitine deficiency.[3,4]

Carnitine deficiency can result from numerous factors, independently or in combination, and will contribute to further sequelae and increased risk factors. Deficiency can result from high fat diets and insufficient supply of precursors for synthesis (methionine, lysine, niacin, vitamins C and B_6). Individuals who have a limited intake of meat and dairy products tend to have lower L-carnitine intakes. However, even long-term vegans usually do not display signs of carnitine deficiency. Seizure disorders, diabetes mellitus, cirrhosis, illness, and infection (e.g., HIV), strenuous exercise, trauma, pregnancy and lactation, and other conditions characterized by increased physiological stress are associated with decreased carnitine levels. A carnitine deficiency can also result from oxygen deprivation, which can occur in some cardiac conditions.[5] Carnitine deficiency may play a role in the development of retinopathy, hyperlipidemia, neuropathy, or complications of diabetes.[6] Many prescription medications may also have an adverse effect on carnitine levels and functions.

Dietary Sources

As implied by its name, carnitine is primarily found in foods of animal origin, and to a lesser extent, in foods of plant origin. Meat, milk, eggs, and dairy products are the richest sources of dietary carnitine intake, with beef being the most abundant. Generally, the redder the meat, the higher is the carnitine content. Cereals, fruit, and vegetables are relatively poor dietary sources.

Nutrient Preparations Available

Carnitine is administered as one of three salts of L-carnitine: L-carnitine (for heart and other conditions),

propionyl-L-carnitine (for heart conditions), and acetyl-L-carnitine (for Alzheimer's disease). The dosage is the same for all three forms, typically 500 mg to 1 g three times daily.

Note: Only pure L-carnitine should be used as a supplement or therapeutic agent.

Dextrocarnitine (D-carnitine), or the DL-mixture, may interfere with the normal function of the levo (L-) isomer and produce signs of deficiency.

Dosage Forms Available

Capsule, powder, tablet.

Source Materials for Nutrient Preparations

Synthesized.

Dosage Range

Adult

Dietary: No dietary reference intake (DRI) or recommended dietary allowance (RDA) has been established for carnitine. The average omnivorous diet provides approximately 100 to 300 mg of carnitine per day.
Supplemental/Maintenance: 1500 to 4000 mg per day in divided doses, when supplementation is indicated. Optimal levels of intake have not been established.
Pharmacological/Therapeutic: 150 mg to 1 g three times daily.
Toxic: No toxicities have been reported or suspected as being associated with carnitine.

Pediatric (<18 Years)

Dietary: No DRI or RDA has been established for carnitine.
Supplemental/Maintenance: Usually not necessary, although often administered to LBW infants (preterm or full term) with breast milk or infant formula and in children receiving long-term total parenteral nutrition (TPN). Optimal levels of intake have not been established.
Pharmacological/Therapeutic: 50 mg to 1 g three times daily. One clinical trial involving children diagnosed with ADHD used 50 mg/kg twice daily, up to a maximum of 4 g daily.[7]
Toxic: No reported adverse effects have been specifically related to children.

SAFETY PROFILE

Overview

L-Carnitine is quite safe, with no significant adverse effects reported, even at high doses.

Nutrient Adverse Effects

General Adverse Effects

Rarely, gastrointestinal (GI) complaints such as nausea and vomiting have been reported with the use of L-carnitine.[8] Sleeplessness may occur if taken before bed.

Pregnancy and Nursing

Adverse effects are not predicted, and reports are lacking. However, the lack of controlled studies involving pregnant or lactating women prevents any claims of safety and suggests that supplementation should be avoided during such life stages.

Infants and Children

Adverse effects are not predicted, and reports are lacking. Supplementation is not recommended unless otherwise indicated as essential.

Contraindications

Individuals with low or borderline-low thyroid levels should avoid carnitine supplementation because it may impair the action of thyroid hormone.[9,10] This proposed effect is primarily extrapolated from research involving patients being treated for goiter with exogenous hormone.

Precautions and Warnings

DL-Carnitine may produce muscle weakness; the D isomer should be avoided because it may interfere with the activity of L-carnitine and thus is potentially toxic.

INTERACTIONS REVIEW

Strategic Considerations

The activity of carnitine suggests significant potential in preventing and treating many conditions, particularly in supporting healthy cardiovascular function. Combination therapy with a statin drug can be particularly effective in reducing lipoprotein(a) levels, especially in patients with type 2 diabetes. However, several common medications and drug classes can increase carnitine excretion or interfere with its activity. Continued development of carnitine therapy in treatment of ischemic disease is probable given its potential to limit anoxic damage while simultaneously reducing peripheral arterial resistance.[11] Furthermore, it may inhibit platelet-activating factor (PAF), thus potentially contributing an antithrombotic effect. Arterial insufficiency can decrease carnitine content of heart muscle cells. Carnitine is used conventionally in critical care and cancer surgery and has been found to benefit elderly and other high-risk patients undergoing elective cardiac surgery.[12]

In regard to neurological conditions and carnitine, emerging evidence supports further research into its value in treating individuals with Alzheimer's disease.[13] Anticonvulsant medications tend to increase carnitine excretion, thus suggesting a potential role for coadministration in seizure disorders. Its immune-enhancing activity and potential efficacy during infections is countered by the adverse effects exerted on it by some chemotherapeutic agents and antiviral drugs, especially antiretroviral nucleoside analogs. Carnitine inhibits entry of thyroid hormone into certain cells and can be used to prevent adverse effects of thyroid therapy for goiter.[9,10]

NUTRIENT-DRUG INTERACTIONS

Effect and Mechanism of Action

Carnitine is essential for intramitochondrial metabolism of long-chain fatty acids. Researchers have proposed that Duchenne muscular dystrophy (DMD) involves alterations leading to blockage of the inosine monophosphate (IMP) to adenylsuccinate purine pathway. Allopurinol inhibits xanthine oxidase (thus favoring restoration of IMP synthesis) and slows degradation of purines through its effects on adenosine deaminase and purine nucleotide phosphorylase, two key enzymes.[14] These effects favor restoration of energy charge and thus of membrane integrity, thereby reducing transmembrane losses of essential metabolites. Coadministration of L-carnitine could theoretically benefit individuals with DMD and enhance therapeutic effects of allopurinol.

Research

Individuals with DMD exhibit severely depressed muscle carnitine levels, i.e., approximately 16.5 times lower than in normal subjects.[15] Such patients also exhibit severely depressed levels of all adenine and guanine nucleotides and some of their metabolites, and ATP levels are approximately 40 times lower than in normal subjects.[16] Carnitine deficiency in the muscle of DMD patients may be related to this observed ATP deficiency because muscle cells take up carnitine from the serum by a process of active transport.[17,18]

In the first of several studies, Castro-Gago et al.[14] found that the activity levels of adenosine deaminase and purine nucleotide phosphorylase were more than double in the serum of untreated DMD patients than in normal patients, thus leading to increased rates of purine catabolism. They reported that allopurinol treatment reduces activities to normal or below-normal levels.

Camina et al.[16] determined levels of purines, purine metabolites, related enzymes, and carnitine in muscle of eight untreated DMD patients, 12 allopurinol-treated DMD patients, and 12 age-matched controls. Together with several other beneficial changes to IMP and related metabolites, allopurinol restored acylcarnitine to normal levels, resulting in improved muscle strength, and significantly increased free carnitine levels.

Evidence based on clinical trials is lacking thus far to determine whether L-carnitine coadministration might enhance this beneficial effect of allopurinol and at what dosage level, if any, an adverse additive effect might occur.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Health care professionals treating individuals with DMD are advised to discuss the effects of the disease process on carnitine status and its implications for their health. Administration of allopurinol may constitute a valuable component of a comprehensive therapeutic strategy in the treatment of such individuals. Clinical evidence is lacking to confirm whether concomitant use of carnitine might improve efficacy of such an approach. However, available research indicates that carnitine is unlikely to produce any adverse effects and suggests that muscle function and strength in such patients would generally benefit from increased carnitine levels, which are known to result from carnitine administration.

Doxorubicin and Related Anthracycline Chemotherapy

Evidence: Doxorubicin (Adriamycin, Rubex).
Extrapolated, based on similar properties: Daunorubicin (Cerubidine), epirubicin (Ellence, Pharmorubicin), idarubicin (Idamycin, Zavedos), mitoxantrone (Novantrone, Onkotrone).
Similar properties but evidence lacking for extrapolation: Daunorubicin, liposomal (DaunoXome); doxorubicin, pegylated liposomal (Caelyx, Doxil, Myocet).

Effect and Mechanism of Action

Doxorubicin is a highly effective antineoplastic agent, but cardiotoxicity (acute and chronic) is an adverse effect occurring in up to one third of patients treated after a cumulative dose of 300 mg/m^2 and increasing sharply beyond a cumulative dose of 360 mg/m^2. The resultant irreversible and dose-dependent cardiomyopathy limits its clinical usefulness. Research indicates that doxorubicin inhibits fatty acid oxidation in part secondary to inhibition of carnitine palmitoyl transferase I (CPT-1) and depletion of L-carnitine, its substrate, in cardiac tissue after acute (in vitro) or chronic (in vivo) administration. L-Carnitine also plays a role in fatty acid oxidation independent of CPT-1 or fatty acid chain length. Acute exposure to doxorubicin can cause a concentration- and time-dependent inhibition of CPT-1-dependent long-chain fatty acid oxidation (i.e., of palmitate). Chronic doxorubicin exposure can inhibit palmitate oxidation as much as 40%. Doxorubicin can also acutely inhibit medium- and short-chain fatty acid oxidation, which is independent of CPT-1.[19]

Cardiotoxicity of anthracycline chemotherapy agents is multifactorial and also involves oxidative stress, in part mediated by an iron-catalyzed Fenton reaction; iron-chelating agents have been shown to decrease doxorubicin cardiac toxicity. Two conditions of cardiotoxicity have been recognized. The first is a dose-independent idiosyncratic phenomenon appearing immediately after anthracycline administration and is based on a pericarditis-myocarditis syndrome in patients without previous cardiac disease. The second condition is dose related and characterized by progressive decline of left ventricular systolic function, as assessed by the ejection fraction on nuclear medicine and echocardiographic studies, which may lead to congestive heart failure (CHF). Diastolic dysfunction may also lead to CHF, with or without concomitant compromise of left ventricular ejection fraction. On pathological examination, progressive anthracycline-related cardiac damage may include restrictive endomyocardial disease, characterized by fibrous thickening of the endomyocardium, and dilated cardiomyopathy, as a result of myocardial fibrosis and hypertrophy of surviving myocytes. Symptoms can appear many years after completion of chemotherapy, although sequential assessment

of left ventricular systolic and diastolic function will show compromise long before symptomatic CHF ensues. Risk of anthracycline-induced CHF is increased by radiotherapy fields that involve all or part of the heart.[20-22]

Carnitine is well known for its central roles in fatty acid oxidation, mitochondrial integrity and metabolism, cardiovascular function, and muscle tissue (especially myocardium) metabolism. Its depletion impairs these normal activities, and its presence provides protective effects on these tissues and activities. In particular, acute or chronic administration of L-carnitine may abolish the doxorubicin-induced inhibition of palmitate oxidation and reverse acute inhibition of medium- and short-chain fatty acid oxidation by doxorubicin.[19]

Cardiac toxicity is similar between equipotent doses of doxorubicin and daunorubicin, slightly lower for epirubicin, and only one-sixth that of doxorubicin for equipotent doses of mitoxantrone. Doxil and DaunoXome (liposomal doxorubicin and daunorubicin, respectively) have negligible cardiotoxicity, presumably because of negligible cardiac exposure to the active drug with the pharmacokinetics of the liposome-encapsulated preparation.

Research

A wide range of both in vitro and animal research has demonstrated that L-carnitine can prevent or reduce doxorubicin-related cardiac damage.[23-25] Alberts et al.[26] reported that carnitine significantly decreased doxorubicin-induced cardiotoxicity at both acute high dose and chronic intermittent low dose without decreasing antitumor activity or increasing bone marrow toxicity, based on a mouse model. The findings of an in vitro experiment conducted by Maccari and Ramacci[25] using rat heart tissue indicate that the L-diastereoisomer of carnitine is specific in its reparatory effect against doxorubicin cardiotoxicity, as indicated by heart rate, coronary flow, and contractile force; they noted that the dextrorotatory form (D-carnitine) was totally inactive. These authors ascribed this benefit to the "natural role played by this substance in metabolic processes."

Abdel-aleem et al.[19] investigated the acute and chronic effects of doxorubicin on fatty acid oxidation in isolated cardiac myocytes. Acute exposure to doxorubicin produced a concentration- and time-dependent inhibition of CPT-1-dependent long-chain fatty acid oxidation of palmitate. Chronic doxorubicin exposure (18 mg/kg) inhibited palmitate oxidation 40% and to a similar extent seen in vitro with 0.5 mM doxorubicin. Conversely, acute or chronic administration of L-carnitine completely abolished the doxorubicin-induced inhibition of palmitate oxidation. Furthermore, medium- and short-chain fatty acid oxidation was also inhibited acutely by doxorubicin and could be reversed by L-carnitine, even though they are independent of CPT-1. Doxorubicin also significantly decreased oxidation of the CPT-1-dependent substrate palmitoyl-CoA by 50% in isolated rat heart mitochondria, but only at concentrations greater than 1 mM, which is higher than clinically relevant doxorubicin concentrations.

Similarly, Sayed-Ahmed et al.[28] reported that propionyl-L-carnitine (PLC) reversed cardiotoxic effects in isolated cardiac myocytes and rat mitochondria perfused with doxorubicin (5 mM) without affecting therapeutic effects. For example, daily administration of PLC to doxorubicin-treated rats resulted in complete reversal of drug-induced increase in cardiac enzymes, except lactate dehydrogenase (LDH), which was only reversed by 66%. In cardiac tissue homogenate, doxorubicin caused a significant 53% increase in malonedialdehyde (MDA), a marker of oxidative stress, and a significant 50% decrease in reduced glutathione (GSH), a fundamental intracellular peptide antioxidant; levels. In contrast, PLC induced a significant 33% decrease in MDA and a significant 41% increase in GSH levels. Daily administration of PLC to doxorubicin-treated rats completely reversed the increase in MDA and the decrease in GSH induced by doxorubicin to normal levels. Overall, PLC therapy completely protected against doxorubicin-induced inhibition of mitochondrial beta-oxidation of long-chain fatty acids. PLC also exerted or induced a significant antioxidant defense mechanism against doxorubicin-induced lipid peroxidation of cardiac membranes. PLC did not interfere with the antitumor activity of doxorubicin while providing these beneficial effects.[28]

Mijares and Lopez[29] determined that acute exposure to doxorubicin impaired intracellular Ca^{++} handling and induced a concentration-dependent elevation of diastolic calcium concentration ($[Ca^{++}]$) in isolated cardiomyocytes loaded with fura-2/AM (acetoxymethyl ester). These adverse effects were not prevented by pretreatment with L-carnitine. However, L-carnitine at 10 μM concentration in the culture medium of the cardiomyocytes fully inhibited the increase in $[Ca^{++}]$ induced by this anthracycline derivative. These results indicate that acute exposure to doxorubicin impairs intracellular Ca^{++} handling and that L-carnitine exerts a cardioprotective effect, in part by preventing the doxorubicin-induced elevation in diastolic Ca^{++} concentration.

The cardiotoxicity of doxorubicin can be of rapid onset and endure for decades, often without cardiac complaints. In a longitudinal assessment of cardiac function in 22 patients treated with anthracycline chemotherapy for osteogenic sarcoma or malignant fibrous histiocytoma, Brouwer et al.[30] found systolic dysfunction in more than a quarter of the patients and diastolic dysfunction in almost half after two decades (median, 22 years). Moreover, cardiac dysfunction was progressive, as measured at 9, 14, and 22 years.[30]

Although limited by their small size and preliminary character, clinical trials have similarly found beneficial effects from coadministration of carnitine with doxorubicin therapy. De Leonardis et al.[31] studied nine patients receiving a cumulative dose (200-490 mg/m^2) of doxorubicin using creatine kinase levels to evaluate acute cardiotoxicity and electrocardiography and echocardiography to evaluate myocardial contractility for chronic cardiotoxicity. Based on their findings, they proposed "systematic use of L-carnitine as adjuvant therapy ... during doxorubicin administration" to be cardioprotective. Subsequently, Chavez et al.[32] reported that the cardiotoxic effects of doxorubicin were not observed in children treated with a combination of doxorubicin (cumulative dose, 30-60 mg/kg) and carnitine (1-2 g/day).

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians administering doxorubicin therapy are advised to consider pretreatment and concomitant use of L-carnitine as a safe measure with significant probability of preventing or reducing the cardiotoxic effect of this powerful antineoplastic agent. A typical therapeutic dosage of L-carnitine would be in the range of 1 to 3 g daily, given orally in two divided doses commencing before doxorubicin therapy, continued throughout therapy, and for several years after treatment, especially if the cumulative dose of doxorubicin is greater than 360 mg/m^2, if the patient has also received thoracic radiation with exposure of all or part of the cardiac volume, or if sequential assessment of left ventricular ejection fraction and/or diastolic function reveal significant decline from pretreatment values. L-Carnitine is not a potent antioxidant, as is coenzyme Q10 (ubiquinone), another nutrient that helps abrogate

doxorubicin cardiotoxicity, but which is controversial because at least some of the antineoplastic effect of doxorubicin may be mediated by free-radical production, which can be inhibited by antioxidants. (See Coenzyme Q10 monograph.) The body of evidence indicates that L-carnitine is essentially nontoxic and unlikely to interfere with the efficacy of chemotherapeutic treatment.

Acute cardiotoxicity can be evaluated by creatine kinase, particularly the cardiac-specific MB isoenzyme. Chronic cardiotoxicity can be monitored using electrocardiography and the left ventricular performance by computed M-mode echocardiography measuring the ejection fraction and by MUGA scan (nuclear medicine technique for measuring cardiac ejection fraction), both of which are reliable and highly sensitive, noninvasive parameters for evaluating myocardial contractility.

Anecdotal clinical experience has indicated that therapeutic benefit in existing doxorubicin-induced cardiomyopathy with clinical CHF can be obtained by therapeutic use of L-carnitine, coenzyme Q10, taurine, magnesium, fish oil, and hawthorn *(Crataegus)* leaf/flower and berry extracts, at least in some cases. Conventional pharmacological management includes angiotensin-converting enzyme (ACE) inhibitors, diuretics, and sometimes digoxin. Integrative management with these nutrients, botanicals, and pharmaceuticals may be of greatest clinical benefit when applied by individuals experienced both in nutritional and conventional medicine. Randomized controlled clinical trials in this area would be of great interest.

Isotretinoin and Related Retinoids

Evidence: Isotretinoin (13-cis retinoic acid; Accutane).
Extrapolated, based on similar properties: Acitretin (Soriatane), bexarotene (Targretin), etretinate (Tegison), tretinoin (All-Trans-Retinoic Acid, ATRA, Atragen, Avita, Renova, Retin-A, Vesanoid, Vitinoin).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability:	Evidence Base:
4. Plausible to **2. Probable**	○ **Preliminary** to ◉ **Emerging**

Effect and Mechanism of Action

The specific mechanism of action underlying the protective effect of carnitine in relation to retinoids is unknown. The hepatotoxic action of isotretinoin can cause abnormalities in liver function, as well as elevations in serum cholesterol and muscle pain and weakness.[33,34] The resultant symptoms are similar to the main characteristics of carnitine deficiency (e.g., myalgia, weakness, hypotension). The growing body of scientific knowledge about the role of carnitine in hepatic detoxification functions should lead to a better understanding of the interaction between carnitine and retinoids.

Carnitine is well known for its central role in fatty acid oxidation in mitochondria and L-carnitine, in particular, serving as the substrate of CPT-1. Two major isoforms of acetyl-CoA carboxylase (ACC) are present in mammals. The 275-kDa beta form (ACC-β) is predominantly in heart and skeletal muscle, whereas the 265-kDa alpha form (ACC-α) is the major isoform in lipogenic tissues such as liver and adipose tissue. ACC-β plays a major role in controlling fatty acid oxidation by means of the ability of malonyl-CoA to inhibit CPT-1, a rate-limiting enzyme of fatty acid oxidation in mitochondria.[35]

Research

Georgala et al.[36] investigated the use of L-carnitine to reduce the adverse effects of isotretinoin, specifically myalgia; 230 patients with cystic acne were treated with isotretinoin (0.5 mg/kg/24 hours). They divided the patients who reported muscular symptoms into two groups; 20 subjects received L-carnitine (100 mg/kg/24 hours orally), and another 20 received placebo. Among these patients, they noted that carnitine blood levels (both total and free, acylcarnitine) were "remarkably decreased at the onset of their muscular symptoms," along with "the well known increases of their liver enzymes and lipids." Furthermore, among those patients receiving isotretinoin but not reporting myalgia, they found that laboratory tests showed elevated liver enzymes and lipids along with a decrease in blood carnitine levels and a "remarkable increase" of urinary carnitine excretion. Subjects receiving concomitant L-carnitine, without isotretinoin discontinuation or reduction, reported the disappearance of their muscular symptoms within 5 to 6 days and exhibited normalization in liver enzymes and carnitine levels at the 45th day of their combined therapy. In contrast, the patients who received placebo along with the isotretinoin continued to report myalgias.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing retinoids are advised to monitor liver enzymes, blood lipids, and carnitine levels and to request that patients report any adverse symptoms characteristic of retinoid toxicity. Prophylactic coadministration of L-carnitine provides a safe protective measure with a reasonable probability of efficacy. A typical therapeutic dosage of L-carnitine would be 1 to 2 g daily, given orally in two divided doses.

Levothyroxine and Related Thyroid Hormones

L-Triiodothyronine (T_3): Cytomel, liothyronine sodium, liothyronine sodium (synthetic T_3), Triostat (injection).
Levothyroxine (T_4): Eltroxin, Levo-T, Levothroid, levothyroxine (synthetic), levoxin, Levoxyl, Synthroid, thyroxine, Unithroid.
L-Thyroxine and L-triiodothyronine ($T_4 + T_3$): animal levothyroxine/liothyronine, Armour Thyroid, desiccated thyroid, Westhroid.
L-Thyroxine and L-triiodothyronine (synthetic $T_4 + T_3$): Euthroid, Euthyral, liotrix, Thyar, Thyrolar.
Dextrothyroxine (Choloxin).

Interaction Type and Significance

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**
⊕✗ **Bimodal or Variable Interaction, with Professional Management**
☼ **Prevention or Reduction of Drug Adverse Effect**

Probability:	Evidence Base:
4. Plausible to **2. Probable**	◉ **Emerging** to ● **Consensus**

Effect and Mechanism of Action

Carnitine may partially block activity of thyroid hormone, at least in part by inhibiting thyroid hormone entry into the nucleus of hepatocytes, neurons, and fibroblasts.[9] Cellular levels of L-carnitine decrease in several diseases, including hyperthyroidism.[37]

Thyroid hormone controls carnitine status through modifications of gamma-butyrobetaine hydroxylase activity and gene expression. In particular, thyroid hormones interact with lipid metabolism by increasing long-chain fatty acid oxidation through activation of carnitine-dependent fatty acid import into mitochondria. Thyroid hormones also increase carnitine bioavailability.[38]

Research

Based on animal experiments and unblinded studies in a few hyperthyroid patients from about 45 years ago, carnitine has been considered a peripheral antagonist of thyroid hormone action, at least in some tissues. More recent research has clarified and expanded scientific knowledge of the physiological properties underlying this interaction. Salvatore Benvenga, MD, and fellow researchers at the University of Messina, School of Medicine, Italy, have conducted extensive research into various aspects of the interaction between carnitine and thyroid hormone.

Data from in vitro experiments by Benvenga et al.[9] using three thyroid hormone–responsive cell lines demonstrate that carnitine acts as a peripheral antagonist of thyroid hormone (TH) action, with a site of inhibition at or before the nuclear envelope. These researchers noted: "We are aware of no inhibitor of TH uptake that has such a markedly different effect on the nuclear versus whole-cell uptake."

In an early uncontrolled study, DeFelice and Gilgore[39] observed clinical amelioration of thyrotoxicosis based on the antagonistic effect of carnitine in hyperthyroidism. In a randomized, double blind, placebo-controlled clinical trial involving 50 women being treated for benign goiter under a fixed, thyroid-stimulating hormone (TSH)–suppressive dose of L-T_4 for 6 months, Benvenga et al.[10] demonstrated that 2 or 4 g/day oral L-carnitine both reversed and prevented symptoms of hyperthyroidism and exerted a beneficial effect on bone mineralization. They also proposed its use in the treatment of thyroid storm. Thus, they concluded that "hyperthyroidism depletes the body deposits of carnitine and since carnitine has no toxicity, teratogenicity, contraindications and interactions with drugs, carnitine can be of clinical use."

Report

Benvenga et al.[40] published a report describing the case of a hyperthyroid patient taking low doses of a conventional antithyroid drug, methimazole (10-15 mg/day), and L-carnitine (2 g/day in two doses) who survived three successive storms, which were associated with potentially life-threatening precipitating factors (post–influenza myocarditis and thrombophlebitis). They remarked that "although L-carnitine does not prevent relapses of thyrotoxicosis, its use should be considered in thyrotoxic patients when intervening factors may precipitate a thyroid storm."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating patients with hyperthyroidism, endogenous or iatrogenic, are advised to consider administering oral L-carnitine with dosage in the range of 1 to 2 g twice daily. Such administration can reverse carnitine depletion associated with hyperthyroid states and support cardiovascular health, which is often compromised in such cases. Confirmatory clinical trials are lacking, but prudence suggests caution in administration of carnitine to individuals with low or borderline thyroid status. Physicians prescribing thyroid hormone are advised to query patients as to supplement use and counsel avoidance of concomitant carnitine. Regular monitoring is appropriate when both agents are clinically indicated.

Nitroglycerin and Related Nitrates

Nitroglycerin (glyceryl trinitrate, GTN; Deponit, Minitran, Nitrek, Nitro-Bid, Nitro-Dur, Nitro-Time, Nitrodisc, Nitrogard, Nitroglyn, Nitrolingual, Nitrol, Nitrostat, Transderm-Nitro, Tridil).

Extrapolated, based on similar properties: Isosorbide dinitrate (ISDN, Isordil, Sorbitrate); combination drug: hydralazine and isosorbide dinitrate (BiDil); isosorbide mononitrate (Imdur, ISMN, ISMO, Isotrate, Monoket).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

Probability:
4. Plausible or
2. Probable

Evidence Base:
○ **Preliminary** to
◉ **Emerging**

Effect and Mechanism of Action

An additive pharmacological effect, as well as a broader supportive synergy, appears to be involved in the combined use of L-carnitine and glyceryl trinitrate (nitroglycerin), although specific research is lacking as to the mechanism(s) of action. DeFelice and Kohl[41] have proposed that is one of several possible mechanisms for L-carnitine's benefit in cardiac ischemia and infarction. Nitroglycerin vasodilates, reduces cardiac afterload (i.e., work), and thus increases oxygen availability to ischemic myocardium. Increasing carnitine availability may prevent a limited availability of fatty acids and ketoacids for beta-oxidation and ATP production within cardiac myocytes, which depend exclusively on this fuel source. If nitroglycerin restores oxygen, and carnitine restores fuel, the metabolic processes will function more effectively.

Research

Several clinical trials have demonstrated that carnitine administration contributes to reduced angina symptoms and related cardiac events and decreased usage of antianginal medications, particularly glyceryl trinitrate. Garzya and Amico[42] reported that oral L-carnitine, 2 g/day, was associated with reduced anginal attacks and decreased glyceryl trinitrate consumption. In experiments with models of myocardial infarction, Tishkin et al.[43] "established that carnitine chloride reduced the size of an ischemic zone, prevented oxidative metabolism, lowered ATP and creatine phosphate levels, inhibited lactate and free fatty acid accumulation in the ischemic myocardium." They also found that concomitant administration of carnitine chloride "with nitrong and isoptin increased the anti-ischemic potency of the former."

In a 1983 review of natural physiological agents in the management of acute myocardial infarction, McCarty[44] proposed that carnitine infusion could improve the bioenergetics of ischemic myocardium by relieving inhibition of mitochondrial adenine nucleotide.

Cacciatore et al.[45] conducted a randomized controlled trial involving 200 patients, 40 to 65 years of age, with exercise-induced stable angina that investigated the therapeutic

effect of L-carnitine (2 g/day) in conjunction with their already-instituted therapy over a 6-month period. Compared with the control group, the patients receiving carnitine demonstrated a significant reduction in the number of premature ventricular contractions at rest, as well as an increased tolerance during ergometric cycle exercise, as demonstrated by an increased maximal cardiac frequency, increased maximal systolic arterial blood pressure, and therefore also increased double cardiac product and reduced ST-segment depression during maximal effort. These changes were accompanied by a reduction in the consumption of cardioactive drugs and improvement in cardiac function and resultant performance, as shown by an increase in the number of patients belonging to class I of the New York Heart Association (NYHA) classification. Furthermore, plasma lipid levels showed improvement laboratory analysis. These researchers concluded that "L-carnitine undoubtedly represents an interesting therapeutic drug for patients with exercise-induced stable angina."

In isometric contraction experiments using rabbit thoracic aorta and cultured bovine aortic endothelial cells (BAEC), Inoue et al.[46] investigated the effect of palmitoyl-L-carnitine (PLC) on endothelium dependent relaxation. They observed that PLC (1-20 μM) inhibited endothelium-dependent relaxation induced by acetylcholine and substance P in a dose-dependent manner, while having no effect on resting tension and glyceryl trinitrate–induced relaxations. Furthermore, although bradykinin, another endothelium-dependent relaxant, induced a biphasic Ca^{++} transient in BAEC, pretreatment of these cells with PLC (5-10 μM) inhibited bradykinin-induced Ca^{++} transients. The authors concluded that the inhibitory effect of PLC on endothelium-dependent relaxation results from the suppression of the intracellular calcium signal transduction in endothelial cells and speculated that PLC "may be an important mediator of the impaired vascular endothelial function in myocardial ischaemia."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating patients with angina are advised to consider administering oral L-carnitine, 1 to 2 g twice daily, in concert with nitroglycerin or related intervention. Although further research through well-designed clinical trials is warranted, the available evidence indicates that the established benefits of carnitine administration on cardiac health, particularly myocardial mitochondrial function, may combine effectively with conventional therapies such as nitroglycerin. Physicians treating patients with angina or related cardiovascular conditions are advised to discuss the potential benefits of carnitine administration and the possible advantages of combining it with their conventional therapies. Nevertheless, even though carnitine is generally considered as essentially nontoxic, regular monitoring is appropriate given the slight (and unproven) risk of an excessive additive response contributing to destabilization.

Coordination of care between health care professionals trained and experienced in both conventional pharmacology and nutritional therapies may provide for the most safe and effective approach to integrative therapeutics. Concomitant use of coenzyme Q10, taurine, magnesium, fish oil, and hawthorn *(Crataegus)* leaf/flower and berry extracts may also be appropriate in some cases.

Pivalate Prodrugs

Cefcapene pivoxil, cefditoren pivoxil (Spectracef), cefetamet pivoxil, pivampicillin (Pondocillin), pivmecillinam (Selexid).
Extrapolated, based on similar properties:
Adefovir dipivoxil (experimental anti-viral drug, with activity against hepatitis B and other viruses).
Pivanex (pivalate prodrug of butyrate, experimental cancer drug).

Interaction Type and Significance

≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**

Nutrient Depletion Probability:	Evidence Base:
4. Plausible or **2. Probable**	▽ **Mixed** to ◉ **Emerging**

Coadministration Benefit Probability:	Evidence Base:
4. Plausible to **2. Probable**	▽ **Mixed** to ◉ **Emerging**

Effect and Mechanism of Action

Pivalate (trimethylacetic acid) is used to generate prodrugs to increase oral bioavailability. After oral administration, all pivalate prodrugs are broken down in the GI tract during absorption and hydrolyzed to pivalic acid and the active agent by nonspecific esterases present in most body tissues. The resultant pivaloyl moiety causes carnitine depletion through the increased urinary excretion of carnitine as pivaloylcarnitine.

After hydrolysis of the prodrug, pivalate (as with other carboxylic acids) can be activated inside cells for further metabolism by acyl-CoA synthases to form pivaloyl-CoA. However, unlike other coenzyme A thioesters, pivaloyl-CoA cannot be oxidized to carbon dioxide in human cells. Consequently, pivaloyl-CoA accumulates in cells and acts as a substrate for a variety of acyl-CoA transferases. The kidneys are primarily responsible for excreting the pivaloyl conjugates that are generated by reactions. Subsequently, the dominant route of pivalate elimination is through formation and urinary excretion of pivaloylcarnitine. This increased carnitine excretion introduces potentially significant risk of perturbing normal cellular function because of the important roles of carnitine in cellular homeostasis.[47]

Research

The increased carnitine excretion caused by pivalate prodrugs is generally accepted as axiomatic. Carnitine deficiency or inborn errors of metabolism resulting in significant carnitine deficiency are among the standard contraindications for pivalate prodrugs. It is generally agreed that long-term treatment or frequently repeated treatment courses using pivalate prodrugs should be used with caution because of increased excretion of carnitine in urine and a reduction of serum carnitine. Nevertheless, the clinical significance of this interaction, the characteristics of patients at increased risk for depletion and adverse sequelae, and the conditions and factors influencing such effects remain unresolved and occasionally controversial.

The limited duration of therapy using most drugs made with pivalic acid and the availability of carnitine from endogenous synthesis and dietary sources reduce the probability of clinically significant carnitine depletion in most cases. Tissue total carnitine content will only be impacted as the urinary losses are sustained over time, and several months of continued pivalate exposure will usually be necessary to impact the liver carnitine pool significantly and lead to depletion of the large muscle carnitine stores. However, Holme et al.[48] note that

patients with carnitine deficiency can have serious, even fatal, clinical manifestations and caution that the "risk of adverse effects from prodrugs that give rise to pivalic acid should be seriously considered, particularly in patients under metabolic stress."

For example, treatment with pivalic acid–liberating antibiotics (e.g., pivampicillin) for 22 and 30 months in children resulted in total muscle carnitine depletion to 10% of reference values. However, no adverse clinical effects were observed or reported, which could be associated with primary or secondary carnitine deficiency. Serum carnitine was significantly reduced after pivampicillin treatment at the highest recommended doses for 7 to 10 days, but levels returned to the normal range within 2 weeks after discontinuing the medication. Despite these reductions in serum carnitine, total body stores of carnitine were reduced by approximately 10%. Thus, the increased excretion of carnitine associated with the use of pivampicillin and other pivalate prodrugs is considered to be without clinical significance in short-term treatment. The frequency with which adverse effects that could be related to carnitine deficiency occur is similar to that of other antibiotics not liberating pivalic acid.[47]

A study conducted by Diep et al.[49] found that replenishment of carnitine levels using normal dietary sources was slow after long-term treatment with pivalate antibiotics. Long-term treatment with pivampicillin and pivmecillinam for 6 to 24 months in five adults and one child reduced the total serum carnitine concentrations to 3.7 to 14.0 μmol/L (reference value: 25-66 μmol/L). In two cases, muscle carnitine was reduced to 0.3 to 0.7 μmol/g wet weight (reference value: 3-5 μmol/g). All patients reported asthenia and muscle symptoms with weakness and pain. One patient developed signs of carnitine depletion in the liver. Serum carnitine levels recovered slowly after cessation of therapy and reached normal concentrations after 6 to 12 months on a normal diet without carnitine supplement. All symptoms caused by carnitine depletion disappeared after the serum carnitine reached 20 μmol/L.

The effects of pivalic acid on carnitine can adversely impact mitochondrial function and metabolic processes in muscles, lungs, and other tissues. In a preliminary study, researchers observed that carnitine administration was associated with preferential elimination of pivalate through formation of pivaloylcarnitine.[50] Subsequently, in a study involving 10 children, Melegh et al.[51] coadministered carnitine (1 g/day) during the latter 4 days of an 8-day course of pivampicillin. Pivampicillin treatment was associated with formation and urinary excretion of pivaloylcarnitine, and administration of carnitine aided the elimination of pivalate as its carnitine ester. These researchers observed that pivampicillin treatment resulted in inhibited oxidation of fats as metabolic fuel and increased utilization of carbohydrates, but that carnitine partially reversed this drug effect by promoting the elimination of the pivaloyl moiety from the body.

Abrahamsson et al.[52] administered pivaloyl-conjugated antibiotics to healthy subjects for 54 days to study the effect of carnitine depletion on physical working capacity. The mean carnitine concentration in serum decreased from 35.0 to 3.5 μmol/L, and in muscle from 10 to 4.3 μmol/g noncollagen protein (NCP). The concentration of 3-hydroxybutyrate in serum slightly increased at submaximal exercise in tests performed before and after 54 days' administration of the drug, an effect attributed to decreased fatty acid oxidation in the liver. Consumption of muscle glycogen also decreased, suggesting decreased glycolysis in the skeletal muscle. However, the concentration of ATP and creatine phosphate did not significantly decrease during exercise, indicating that adequate energy was available for muscle function. Carnitine depletion appeared to affect cardiac function given observed reductions in the work at maximal oxygen uptake and maximal heart rate. Cardiac muscle is an obligate user of fatty acid beta-oxidation as its fuel source (which requires carnitine for transport), as opposed to skeletal muscle, which stores glycogen for anaerobic glycolysis as its initial fuel source.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

In most cases, physicians prescribing pivalate prodrugs for short-term use can safely assume that these medications will not cause clinically significant carnitine depletion. Conventional practice does not recommend either measurement of serum carnitine or concomitant administration of prophylactic carnitine as a general measure for patients prescribed pivalic acid–liberating prodrugs for short-term (acute) use. Almost 1 billion treatment days experience with pivalate prodrugs was accumulated worldwide between 1996 and 2001. Despite such widespread usage, published reports of clinical toxicity have been limited to patients with long-duration treatment.

Coadministration of L-carnitine may be appropriate during treatment with these medications in patients demonstrating or at risk for carnitine deficiency or diagnosed with cardiovascular disease, seizure disorder, or HIV infection. Such protective use is generally considered safe and unlikely to interfere with drug efficacy. If used, administration of at least fourfold molar excess of carnitine (vs. pivalate) is advisable,[53] which in most cases would be adequately provided by 1.5 to 2 g twice daily. Notably, pivalate prodrugs intended for chronic use, such as the antiretroviral adefovir dipivoxil, incorporate carnitine as part of the dosing regimen.[54]

Several important cautions and contraindications arise from the possible adverse effects of these medications on carnitine status. Pivalate prodrugs should be avoided in patients with known or suspected carnitine deficiency. Prudence suggests that use of pivalate prodrugs be avoided in children less than 3 months of age because endogenous carnitine production may not yet be fully developed during the first months of life. Concurrent treatment with valproic acid is also contraindicated, especially in children. In Sweden, pivampicillin is also contraindicated in patients with very small muscle mass. Selection of alter-native pharmacological agents may also be judicious in some cases.

Simvastatin and Related HMG-COA Reductase Inhibitors (Statins)

Evidence: Simvastatin (Zocor).
Atorvastatin (Lipitor), fluvastatin (Lescol, Lescol XL), lovastatin (Altocor, Altoprev, Mevacor); combination drug: lovastatin and niacin (Advicor); pravastatin (Pravachol), rosuvastatin (Crestor); simvastatin combination drug: simvastatin and extended-release nicotinic acid (Niaspan).

Effect and Mechanism of Action

Interventions to reduce lipoprotein(a) [Lp(a)] concentration are important given its atherogenic/prothrombotic properties and associations with both coronary artery and cerebrovascular disease. Statin therapy, as well as fibrates and resins, are generally considered incapable of reducing Lp(a) levels and may in many cases contribute to an increase in Lp(a) levels, even while lowering total cholesterol and low-density lipoprotein (LDL) cholesterol levels. Among conventional pharmaceutical interventions, only nicotinic acid (2–4 g/day) is known to reduce Lp(a). However, L-carnitine can lower plasma Lp(a) levels.

Research

A series of clinical trials conducted by Italian researchers have demonstrated the efficacy of L-carnitine in lowering Lp(a) and a synergistic interaction between L-carnitine and statin therapy in lipid-lowering strategies, especially in individuals with type 2 diabetes. In a double-blind, placebo controlled study, Sirtori et al.[55] found that L-carnitine (2 g/day) significantly reduced Lp(a) levels in subjects with hyper-Lp(a) (i.e., serum Lp(a) levels of 40–80 mg/dL). Two years later, in a study involving patients with type 2 diabetes and hyperlipidemia, Brescia et al.[56] reported that combined therapy with simvastatin (20 mg/day) and L-carnitine (2 g/day) demonstrated greater lipid-lowering efficacy than simvastatin alone, particularly in lowering triglyceride levels. Subsequently, in a trial involving 94 subjects newly diagnosed with type 2 diabetes mellitus being managed through dietary restriction alone, Derosa et al.[57] observed significantly lower plasma Lp(a) levels, compared with placebo, after 3 and 6 months of L-carnitine (2 g/day). Based on these findings, Solfrizzi et al.[58] conducted an open, randomized, parallel-group study involving 52 patients with type 2 diabetes mellitus, triglyceride serum levels less than 400 mg/dL (<4.5 mmol/L), and Lp(a) serum levels greater than 20 mg/dL (>0.71 mmol/L). Subjects were randomized into two groups of equal size and administered either simvastatin alone (20 mg/day) or simvastatin plus L-carnitine (2 g/day) orally for 60 days. The investigators reported that "Lp(a) serum levels increase[d] from baseline to 60 days in the simvastatin group alone versus a significant decrease in the combination group." No differences between the two groups were observed regarding LDL cholesterol, non-HDL cholesterol, and apoB serum levels. The consistent pattern of evidence from these trials indicates that the combination of L-carnitine with statin therapy can enhance therapeutic management of hyperlipidemia, particularly in individuals with type 2 diabetes.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating individuals with hyperlipidemia characterized by elevated Lp(a), particularly the context of type 2 diabetes, are advised to consider a comprehensive approach founded on regular exercise and a healthy diet and combining L-carnitine, as well as fish oil, chromium, and niacin (as inositol hexaniacinate), with conventional lipoid management interventions such as statin therapy. As previously noted, L-carnitine is unlikely to produce any adverse effects on the therapeutic action of a statin drug and may in fact mitigate potential adverse effects on Lp(a) status. Enthusiastic support for improved diet, invigorating exercise, and other healthy lifestyle changes are fundamental to an effective integrative strategy for optimizing healthy function, reversing patterns of dyslipidemia and dysglycemia, and reducing risk of cardiovascular disease.

Valproic Acid and Related Anticonvulsant Medications

Evidence: Divalproex semisodium, divalproex sodium (Depakote), sodium valproate (Depacon), valproate semisodium, valproic acid (Depakene, Depakene Syrup).

Effect and Mechanism of Action

Significant but incomplete evidence indicates that valproic acid (VPA) depresses renal absorption of both free carnitine and acylcarnitine. Other anticonvulsants appear to depress renal absorption of acylcarnitine only. Carnitine depletion may play a central role in the hepatotoxicity of VPA as well as the interference with fatty acid oxidation widely recognized as an adverse effect of VPA. Antiepileptic drugs (AEDs) may also affect carnitine and its functions by other mechanisms.

Research into the pharmacokinetics of VPA's adverse impact on free-carnitine levels suggest accelerated hepatic degradation of VPA as a result of enzyme induction with VPA metabolism.[59] VPA is extensively metabolized by the liver through glucuronic conjugation and oxidative pathways (P450) to produce biologically active metabolites. Half-life can range from 5 to 24 hours because of first-order kinetics. The three major metabolites of VPA are 2-EN-VPA, 4-EN-VPA, and propionic acid derivatives. The 4-EN-VPA may mediate reversible hepatotoxicity, which causes elevation of aminotransferases. Propionic acid derivatives may precipitate hyperammonemia by three different mechanisms, one of which is by interacting with carnitine, acting as a mitochondrial cofactor in the transport and metabolism of long-chain fatty acids.[60]

In treatment of acute VPA toxicity, including coma, L-carnitine's mechanism of action is hypothesized to derive from its ability to decrease elevated ammonia levels. Carnitine coadministration may counterbalance adverse drug effects of extended AED therapy, but such benefit may vary depending

on the agent(s) being used, dosing and duration of therapy, patient age and health status, initial carnitine balance, and other factors.

Research

The body of evidence investigating interactions between anticonvulsant medications and carnitine is strong and largely consistent in its findings, but conclusive assessment of clinical implications is difficult because of significant limitations in the research. Carnitine depletion characterizes most of the medications in this drug class, or at least many of the patients. However, many studies failed to assess carnitine status before initiation of anticonvulsant therapy. Broader evidence suggests that individuals prescribed these medications may already be at higher risk for preexisting compromised carnitine status.[1,61]

Valproic acid causes carnitine deficiency, notably in infants and children with epilepsy. Prolonged treatment with VPA, more than other anticonvulsants, enhances renal losses of carnitine esters, lowers serum carnitine levels, and results in secondary carnitine deficiency. In most cases these decreased carnitine levels have no obvious pathological significance, and most children manifest no symptoms of carnitine deficiency. However, anticonvulsant-induced depletion may occasionally cause symptoms of carnitine deficiency such as severe cardiac dysfunction. Typical adverse effects reported in patients treated with VPA include anemia, fatigue, hyperammonemia, hypotonia, lethargy, unexplained stupor, and carnitine-responsive cardiomyopathy. Recurrent episodes of a Reye's-like syndrome with low concentrations of carnitine in liver and muscle, reduced plasma glucose levels, and ketone bodies are among the most serious consequences of carnitine depletion.[62] Coulter[63] hypothesized in a 1984 letter that carnitine depletion plays a central role in VPA's hepatotoxicity. Dreifuss and Langer[62] proposed that the risk of AED-related liver damage increases in children under 24 months of age. Melegh and Trombitas[64] described lipid globule accumulation with ultrastructural abnormalities of mitochondria in the skeletal muscle of seven children treated with VPA. They attributed these lipid deposits to inhibited mitochondrial fatty acid oxidation, a carnitine-dependent process.

Several preliminary studies and controlled trials have demonstrated dramatic reductions in serum carnitine levels and related adverse effects associated with anticonvulsant medications, especially among pediatric patients receiving multidrug therapy. Morita et al.[65] measured decreases in the serum concentrations of total and free carnitine in patients who had received multiple doses of AEDs, especially those receiving sodium valproate, but also those receiving other medications. Nevertheless, no abnormal losses of carnitine in urine were observed. Several factors that may be relevant to the hypocarnitinemia were surveyed statistically. Further analysis revealed that in all the patients, levels of total carnitine and free carnitine were inversely correlated with the dosages of sodium valproate, and that dosage of sodium valproate was the most critical negative contributor to carnitine status. Furthermore, these researchers found that poor muscle volume and coadministration of phenytoin with sodium valproate enhanced hypocarnitinemia. Rodriguez-Segade et al.[66] conducted a study with 183 adult outpatients and 49 controls in which 77% of subjects taking VPA demonstrated a deficiency of free carnitine (i.e., >2 SD below the mean). In contrast, such deficiency was observed in 27% of subjects receiving combined phenytoin-phenobarbital therapy, 23% taking carbamazepine, and 16% receiving phenytoin monotherapy.

In a clinical trial involving 37 children, Zelnick et al.[67] assessed blood carnitine levels before and after therapy using several different anticonvulsant medications. They found that carnitine levels decreased significantly from baseline values only in children receiving VPA; total blood carnitine dropped from 45.3 μM before treatment to 34.9 μM after treatment among those subjects. In contrast, total blood carnitine dropped from 45.7 μM pretreatment to 43.4 μM posttreatment among subjects administered carbamazepine and from 44.9 μM pretreatment to 42.1 μM posttreatment among subjects in the phenobarbital group.[68] Castro-Gago et al.[68] measured serum carnitine levels in 32 epileptic children before and during treatment with VPA, carbamazepine, and phenobarbital. They found that both free-carnitine and total-carnitine levels declined significantly with respect to pretreatment levels in all three treated groups. Levels dropped most markedly and consistently in the VPA-treated group, 35% of whom exhibited carnitine deficiency (i.e., total carnitine <30 μmol/L) by the twelfth month of treatment. In none of the three groups were serum carnitine levels significantly correlated with the serum concentration of the anticonvulsant drug. Based on these findings, the authors recommended that physicians prescribing any of these drugs to children monitor their serum carnitine levels.

In contrast, Hug et al.[69] studied 471 children of various ages on eight variations of AED monotherapy and polytherapy (with 32 healthy controls, age 1 to 16 years). They found that phenobarbital monotherapy more significantly reduced carnitine levels than VPA monotherapy. "Only for phenobarbital was there an inverse correlation between the serum concentration of the drug and that of carnitine concentration." Total carnitine and free carnitine were deficient in the following percentages of patients receiving AED monotherapy: phenobarbital (36% total; 21% free), VPA (23% total; 9% free), phenytoin (12% total; 8% free), and carbamazepine (8% total; 1% free). For patients receiving AED polytherapy, the percentages were VPA-carbamazepine (44% total; 22% free), phenobarbital-phenytoin (37% total; 16% free), phenobarbital-carbamazepine (18% total; 6% free). Although both Zelnick et al.[67] and Castro-Gago et al.[68] reported decreased serum carnitine levels among individuals using VPA, Zelnick found no such association for phenobarbital, but Castro-Gago found such an effect. Subsequently, Verotti et al.[70] questioned whether the depletion of carnitine and the increase in blood ammonia levels (both caused by VPA) are actually related to each other. Their investigation found that the depletion of carnitine was significantly more severe when epileptic individuals were taking VPA together with other antiseizure medications.

The risk of carnitine depletion and drug-induced deficiency may reflect the disease severity, broader health condition, and nutritional status of patients being treated with anticonvulsants more than the adverse effects of the medications themselves. De Vivo et al.[71] reviewed many clinical trials demonstrating an association between anticonvulsant therapy and decreased carnitine levels, especially in children and particularly involving VPA. They concluded that younger children (1-10 years) treated with VPA tend to demonstrate a more significant decrease in carnitine concentrations than older children (10-18 years) and advised L-carnitine coadministration in certain cases, particularly infants and young children (especially those <2 years) diagnosed with neurological disorders and receiving VPA and multiple anticonvulsants. Earlier, Van Wouwe[1] had noted that before VPA therapy, plasma free-carnitine values were age dependent and increased during childhood. Hirose et al.[72] conducted a randomized, case-control study involving 45 children with epilepsy, age 6 to 21 years, who were treated with VPA monotherapy and were free of abnormal neurological findings or nutritional problems; an age-matched group of

45 children without epilepsy served as the control group. Although serum VPA concentration exhibited a weak negative correlation with both total and free serum carnitine, there was no significant difference in total and free serum carnitine levels between the VPA-treated and control groups; plasma ammonia levels were the same in the two groups. These researchers concluded that children on a regular diet receive sufficient carnitine intake to adequately meet their daily carnitine requirement, that valproate therapy does not deplete carnitine levels in otherwise healthy children, and that VPA-induced carnitine deficiency is not likely to occur in this population.

Hiraoka et al.[73] studied the pharmacokinetics of decreases in the blood free-carnitine level as an adverse effect of VPA administered to epileptic patients in connection with changes in the VPA disposition. They observed that serum free-carnitine level in patients taking at least one of phenobarbital, phenytoin, and carbamazepine in addition to VPA was significantly lower than that in the group given only these other agents without VPA. Subjects medicated only with VPA also tended to have a lower serum free-carnitine level than controls, although not to a significant degree. Among all the patients taking VPA with or without other AED(s), a significantly positive correlation was observed between the serum free-carnitine level and the value of dose and level ratio (L/D) of VPA. Such findings indicate that both the serum free-carnitine concentration and the L/D value of VPA were remarkably reduced in patients receiving both VPA and another AED. The researchers interpreted these results to suggest that enzyme induction by and accelerated hepatic degradation of VPA plays a role in the reduction of free carnitine levels, which is then reflected in free-carnitine deficiency.

Plasma carnitine levels are often low in people taking VPA for extended periods. Coadministration of carnitine may normalize low carnitine levels associated with anticonvulsant therapy, especially children taking VPA. Even so, concomitant carnitine therapy for patients undergoing long-term AED therapy remains contentious, and research findings have yet to evolve to an established level of consistency, refinement, and clarity to form a consensus or enable formulation of well-founded clinical algorithms. Ohtani et al.[74] compared plasma carnitine and blood ammonia concentrations in 25 severely handicapped patients, age 3 to 21 years, with those of 27 age-matched control subjects. Of the handicapped patients, 14 were treated with anticonvulsant drugs, including VPA; the remaining 11 patients were treated with drugs other than VPA. They found that plasma carnitine concentrations were lower and blood ammonia values were higher in VPA-treated patients than in the untreated patients and control subjects, and that plasma carnitine concentrations exhibited a significant inverse relationship with both VPA dosage and blood ammonia values. Both carnitine deficiency and hyperammonemia were corrected after oral administration of DL-carnitine (50 mg/kg/day) for 4 weeks.

Ater[60] reported that carnitine appeared to be protective against the drug-induced liver damage for which children treated with anticonvulsants are at high risk. Subsequently, Freeman et al.[75] conducted a placebo-controlled, double-blind, crossover study involving 47 children with seizures being treated with either VPA or carbamazepine that attempted to assess changes in "well-being," as perceived by parents, after oral carnitine coadministration (100 mg/kg). They found that well-being scores improved weekly for all children (i.e., when either placebo or carnitine was administered), and that none of the analyses of improved well-being achieved statistical significance. These researchers concluded that available evidence indicated that prophylactic coadministration of carnitine to children taking anticonvulsant medications for alleviating common, nonspecific symptoms was not warranted. Furthermore, they noted that, as of 1994, there were no reliable clinical or laboratory tests for determining symptomatic carnitine deficiency caused by anticonvulsant administration, and that further research was needed to develop methods for identifying children in need of carnitine coadministration.

Melegh, Pap, et al.[76] compared 10 randomly selected subjects with age- and gender-matched controls in a randomized trial measuring energy metabolism in children receiving long-term VPA therapy. Eight of the treated subjects showed an altered fuel consumption pattern, including a significant reduction in the amount of fats oxidized and a shift to increased utilization of carbohydrates. Carnitine coadministration for a month (50 mg/kg/day as oral solution, divided equally into two or three doses) reversed this pattern as the respiratory quotient decreased, oxidation of fats increased, and consumption of carbohydrates decreased. Van Wouwe[1] demonstrated that "prolonged" VPA treatment results in secondary carnitine deficiency in children. He compared samples of plasma drawn at the onset of and after 9 months of continuous VPA treatment in 13 children and found that mean plasma free carnitine decreased by 40%, plasma total carnitine decreased by 20%, and the esterified/free-carnitine ratio increased by 40%. Biochemical evidence of carnitine deficiency appeared in 6 of the 13 subjects, although clinical symptoms, primarily fatigue and excessive sleepiness, were observed in only two. The author concluded that a "dose of 15 mg/kg body weight is effective to reverse the clinical symptoms of carnitine deficiency within a week" and advised carnitine coadministration in children complaining of fatigue during prolonged VPA therapy. He also noted that the "dose to prevent deficiency is not yet established." Gidal et al.[77] found that carnitine (50 mg/kg) protected children from valproate-induced, transient hyperammonemia.

Carnitine therapy may do more than only protect against AED-induced depletion and resulting adverse effects. Research by Sakemi and Takada[78] indicates that concomitant administration of L-carnitine during VPA therapy may potentiate the activity of VPA. They reported that L-carnitine coadministration increased carnitine concentrations significantly in serum and liver but not in the brain, and that the resultant increase of serum free-VPA concentrations by concomitant carnitine apparently caused free-VPA concentrations in the brain to increase. Overall, the research literature reveals an understanding that carnitine has an effect on the performance and toxicity of VPA, but no clear agreement as to a potential therapeutic role for carnitine has emerged.

Currently available clinical trials exhibit mixed and conflicting results and cast doubt on the efficacy of carnitine administration as a generic prescription for individuals taking AEDs. However, no clinical trial has yet addressed the issues of carnitine depletion and carnitine administration over an extended time. These medications are often prescribed for years or decades, and the risk of cumulative depletion patterns and their clinical implications have yet to be adequately addressed. Long-term, well-designed clinical trials are warranted to investigate the adverse effects on carnitine level and function and compensatory concomitant carnitine administration, particularly with reference to specific age groups, contextual pathological and nutritional status, and various anticonvulsant agents. Adequate tools for assessing carnitine status are critical to accurate and clinically applicable findings.

Apart from issues of chronic depletion and corrective replacement therapy, intravenous (IV) carnitine is among the interventions used in acute VPA-induced hepatotoxicity and overdose; high-flux hemodialysis and charcoal hemoperfusion are also used in such situations.[79]

Reports

Several case reports have described VPA-related carnitine deficiency causing abdominal pain in children. For example, Shuper et al.[79] reported on a pediatric patient with intractable epilepsy who had a complete remission of severe VPA-induced abdominal pain immediately after administration of L-carnitine, 300 mg/day.

Houghton and Bowers[80] reported a case of VPA overdose in a woman with polysubstance overdose and a history of alcoholism and hepatitis B and C. Several interventions were necessary to address the multiple toxicities involved and the sequence of risk and immediacy. L-Carnitine at 100 mg/kg/day was administered to correct hyperammonemia and encephalopathy and continued until serum ammonia and VPA levels had normalized.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

In consideration of research available at this time, physicians prescribing valproic acid, phenobarbital, or related anticonvulsant medications may find it prudent to coadminister oral L-carnitine prophylactically or monitor carnitine blood levels and coadminister L-carnitine as indicated. Susceptibility to adverse effects appears to be greater in three groups: infants and young children receiving VPA, patients receiving anticonvulsant polytherapy (especially those <2 years), and individuals with severe neurological conditions, compromised nutritional status, or other medical conditions characterized by compromised liver function or systemic overload. Concurrent treatment with pivalate prodrugs is contraindicated because of increased urinary carnitine excretion. Although higher-dose carnitine (3–7 g/day) likely would prevent deficiency, there is little clinical experience in this area and no available clinical research to serve as a guideline. Serum carnitine levels should be monitored during long-term anticonvulsant therapy. Concomitant administration of L-carnitine may be advisable for some patients. Nevertheless, clinically significant deficiencies of carnitine appear to be uncommon, and no conclusive evidence has confirmed that most individuals benefit from carnitine supplements.

In 1998, a panel of pediatric neurologists and experts on L-carnitine coadministration strongly recommended oral L-carnitine for all infants and children taking VPA, as well as for adults with carnitine deficiency syndromes, people with VPA-induced hepatic and renal toxicity, people on kidney dialysis, and premature infants on TPN. Oral carnitine in three to four divided doses totaling 100 mg/kg, up to a maximum of 2 g/day, represents a consensus dosage level. However, physicians prescribing anticonvulsant medications should advise patients to refrain from starting any supplemental use of carnitine outside the context of regular supervision and close monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics.

In acute VPA toxicity, use of IV L-carnitine remains investigational but can be considered in patients with coma, central nervous system (CNS) depression, evidence of hepatic dysfunction, and hyperammonemia. In such patients, L-carnitine may be initiated at 50 to 100 mg/kg/day (up to maximum dose of 2 g/day) to correct hyperammonemia and encephalopathy. Such therapy would be continued until serum ammonia and VPA levels had normalized.

Zidovudine (AZT) and Related Antiretroviral Agents, Reverse-Transcriptase Inhibitor (Nucleoside)

Evidence: Didanosine (ddI, dideoxyinosine; Videx); dideoxycytidine (ddC, zalcitabine; Hivid), stavudine (d4T, Zerit), tenofovir (Viread); zidovudine (azidothymidine, AZT, ZDV, zidothymidine; Retrovir); combination drugs: zidovudine and lamivudine (Combivir); abacavir, lamivudine, and zidovudine (Trizivir).

Extrapolated, based on similar properties Abacavir (Ziagen), lamivudine (3TC, Epivir).

Effect and Mechanism of Action

Antiretroviral drugs are well known to cause mitochondrial toxicity, peripheral neuropathy, and other significant adverse effects. L-Carnitine normally plays a major role in the transport of long-chain fatty acids across the inner mitochondrial membrane and facilitates the beta-oxidation of fatty acids.

Reduced levels of carnitine in serum and muscle are found in most patients treated with antiretroviral therapy using AZT and related agents. These agents are well known for causing muscle damage, notably mitochondrial myopathy characterized by depletion of mitochondrial DNA, enzymatic defects in the respiratory chain system, poor utilization of long-chain fatty acids, and accumulation of lipid droplets within the muscle fibers.[81–84] Thus, reduced muscle carnitine levels, resulting from decreased carnitine uptake by the muscle, are associated with depletion of energy stores within the muscle fibers.

Destructive changes have been observed in other critical sites. Didanosine (ddI), stavudine (d4T), and zalcitabine (ddC) are relatively strong inhibitors of g-polymerase and thus cause a time- and dose-dependent decrease in the intracellular levels of mitochondrial DNA.[85] Acetyl-carnitine deficiency and impairment of mitochondrial DNA synthesis are also crucial to the pathogenesis of axonal peripheral neuropathy, a severe dose-limiting toxicity often associated with didanosine, zalcitabine, and stavudine.[86,87] With regard to zalcitabine (ddC), ddCDP-choline appears to be the zalcitabine metabolite primarily responsible for mitochondrial toxicity.[87] Carnitine depletion has also been observed in peripheral blood mononuclear cells (PBMCs) of HIV-infected individuals.[88] Disrupted mitochondrial membrane potential

(along with increased oxidant stress) also appears in the CD4 and CD8 cells of asymptomatic HIV-infected subjects with advanced immunodeficiency treated with AZT and ddI.[84]

Coadministration of L-carnitine may restore carnitine levels, correct disrupted mitochondrial transmembrane potential, and decrease apoptotic CD4 and CD8 lymphocytes to support immune function and limit or reverse some of the adverse effects of these medications.

Research

The adverse effects of AZT and related antiretroviral nucleoside analogs, particularly on carnitine levels, have been well established in over a decade of research and clinical observations. Their implications for patient health and therapeutic outcomes have also become increasingly clear.

Several studies published in 1994 focused on carnitine depletion in HIV patients and linked it to the action of antiretroviral nucleoside analogs. In an in vitro study using human muscle tissue, Semino-Mora et al.[84] observed depopulation of Leu-19–positive myotubes and destructive changes in mitochondria, including accumulation of lipid droplets, when exposed to AZT at concentrations of 250 μM and higher. Dalakas et al.[81] examined the degree of neutral fat accumulation and muscle carnitine levels in the muscle biopsy specimens from 21 patients with AZT-induced myopathic symptoms of varying severity. They described a pattern of "DNA-depleting mitochondrial myopathy" associated with zidovudine (AZT) use, which is "histologically characterized by the presence of muscle fibers with 'ragged-red'-like features, red-rimmed or empty cracks, granular degeneration, and rods (AZT fibers)." This muscle cell damage caused by AZT results in accumulation of lipid droplets within the muscle fibers from poor utilization of long-chain fatty acids. Reduced muscle carnitine levels, from decreased carnitine uptake by the muscle, are associated with depletion of energy stores within the muscle fibers. De Simone et al.[86] reported carnitine depletion in PBMCs of 20 male patients with advanced AIDS and normal serum levels of carnitines. Campos and Arenas[83] also published a letter reporting muscle carnitine deficiency associated with AZT-induced mitochondrial myopathy.

Preliminary but growing evidence indicates that the L-carnitine may mitigate mitochondrial toxicity associated with zidovudine (AZT) and other nucleoside analogs, provide independent therapeutic benefits on HIV infection parameters, and complement conventional chemotherapeutic regimens in HIV-infected patients.

In a randomized, placebo-controlled clinical trial involving 20 male patients with advanced AIDS (stage IV-C1), De Simone et al.[86] randomly assigned subjects to receive either oral L-carnitine (6 g/day) or placebo for 2 weeks. AIDS patients exhibited cellular carnitine depletion (with concentrations of total carnitine in PBMCs lower than in healthy controls), even though serum carnitine levels were within normal range. These researchers found that treatment with high-dose L-carnitine was associated with a significant trend toward the restoration of appropriate intracellular carnitine levels and strongly improved proliferative responsiveness by lymphocytes in the S and G_2-M stages to mitogens. They also observed a strong reduction in serum triglycerides in the L-carnitine group at the end of the trial compared with baseline levels, which would be expected from improved efficiency of fatty acid transport and utilization.

In an in vitro experiment using human muscle tissue, Semino-Mora et al.[84] found that the addition of L-carnitine (5 mM) to muscle cultures pretreated with AZT (0.0027 to 135 μg/mL) preserves the integrity and volume of mitochondria, prevents AZT-associated destruction of human myotubes, preserves structural integrity and volume of mitochondria, and prevents the accumulation of lipids.[89] Such findings suggest that L-carnitine provides independent therapeutic benefit through its effects on immune system function rather than on the pathogen itself.[90]

Uncontrolled apoptosis plays a critical role in the loss of T lymphocytes in HIV-infected individuals. The Fas/Fas ligand system and ceramide, an endogenous mediator of Fas-triggered apoptosis, appear to be particularly important in the progression of HIV infection. The signal transduced by the Fas receptor involves the activation of an acidic sphingomyelinase, sphingomyelin breakdown, and ceramide production. Disruption of mitochondrial transmembrane potential is an early, irreversible step in the effector phase of apoptosis that allows identification of an additional pool of lymphocytes irreversibly committed to undergo apoptosis, despite still lacking the morphological features typical of apoptosis. Both in vitro and in vivo research show that L-carnitine inhibits Fas-induced apoptosis and ceramide production.[86,91]

Moretti, Alesse, et al.[91] conducted a series of studies investigating the relationship of carnitine to lymphocyte apoptosis, oxidant stress, and immune function in subjects infected with HIV. In a pilot study, they administered daily infusions of L-carnitine (6 g) for 4 months to 11 asymptomatic HIV-1-infected subjects, who had refused antiretroviral treatment despite experiencing a progressive decline in CD4 counts, and monitored immunological and virological measures (as well as safety) at the start of the treatment and then on days 15, 30, 90, and 150. L-Carnitine administration resulted in an increase in absolute CD4 counts, which was statistically significant on days 90 and 150 ($p = 0.010$ and $p = 0.019$, respectively). They also observed a positive but not significant trend in the change in absolute counts of CD8 lymphocytes and a gradual but strongly significant ($p = 0.001$) decrease in the frequency of apoptotic CD4 and CD8 lymphocytes at the end of the study compared to baseline. Cell-associated levels of ceramide also exhibited a strong decline ($p = 0.001$) at the end of the study. L-Carnitine also corrected previously disrupted mitochondrial transmembrane potential. No evidence of L-carnitine toxicity was observed, and no dose reductions were necessary. There was no clinically relevant change in HIV-1 viremia.

In a subsequent trial involving 20 asymptomatic HIV-infected subjects with advanced immunodeficiency, Moretti et al.[88] compared the effects of either zidovudine (AZT) and didanosine (ddI) or the same regimen plus L-carnitine over 7 months. As previously, they measured immunological and virological parameters at baseline and after 15, 60, 120, and 210 days of treatment. They found significant reductions in apoptotic CD4 and CD8 cells, lymphocytes with disrupted mitochondrial membrane potential, and lymphocytes undergoing oxidant stress in subjects treated with AZT and ddI plus L-carnitine compared with subjects receiving only the antiviral agents. Fas and caspase-1 were downexpressed and p35 overexpressed in lymphocytes from patients of the L-carnitine group. CD4 and CD8 counts and viremia showed no significant difference between the groups. No evidence of toxicity from L-carnitine was recognized. They concluded that coadministration of L-carnitine "is safe and allows apoptosis and oxidant stress to be greatly reduced in lymphocytes from subjects treated with AZT and DDI."

In an in vitro experiment, Rossi et al.[87] investigated mitochondrial toxicity and peripheral neuropathy caused by

2',3'-dideoxycytidine (ddCyd; zalcitabine). 2',3'-Dideoxycytidine 5'-diphosphocholine (ddCDP-choline) is among the metabolites of zalcitabine found in a concentration-dependent manner after incubating human cells with the antiretroviral drug. Uptake of ddCDP-choline into mitochondria is more efficient than dideoxyCTP uptake (the triphosphocholine metabolite), suggesting that ddCDP-choline is the metabolite of zalcitabine responsible for mitochondrial toxicity. Furthermore, these researchers reported that, in the cell-free system investigated, 3.0 mM L-carnitine inhibited the uptake of both ddCTP and ddCDP-choline by mitochondria, and when added to U937 cells grown in the presence of 0.25 μM zalcitabine, 3.0 mM L-carnitine partially abrogated the mitochondrial toxicity of zalcitabine.

Nevertheless, in a 2003 review of antiretroviral nucleoside analog reverse-transcriptase inhibitors (NRTIs), Walker[85] concluded that "in established mitochondrial toxicity, cessation of the offending NRTI remains the most effective therapeutic intervention because vitamin cocktails and L-carnitine have, at best, only a marginal effect." He also notes: "Mitochondrial toxicity cannot yet be adequately monitored and predicted."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating HIV-infected individuals may provide therapeutic benefit by administering L-carnitine regardless of whether they are prescribing AZT or other nucleoside analogs concurrently. Findings from clinical trials and related research support the significant probability that concomitant carnitine therapy may enhance immune function, mitigate the pathological process, prevent the development of myotoxicity, and reduce adverse effects of conventional antiviral therapies. A typical therapeutic dosage of L-carnitine would be in the range of 1 to 3 g daily. However, a large proportion of patients may require an initial dosage of up to 6 g daily to restore carnitine levels, especially if they have become depleted by antiviral medications. The body of evidence indicates that L-carnitine is essentially nontoxic and unlikely to interfere with the efficacy of conventional treatment.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Calcium Channel Blockers

Amlodipine (Norvasc); combination drug: amlodipine and benazepril (Lotrel); bepridil (Bapadin, Vascor), diltiazem (Cardizem, Cardizem CD, Cardizem SR, Cartia XT, Dilacor XR, Diltia XT, Tiamate, Tiazac), felodipine (Plendil); combination drugs: felodipine and enalapril (Lexxel); felodipine and ramipril (Triapin); gallopamil (D600), isradipine (DynaCirc, DynaCirc CR), lercanidipine (Zanidip), nicardipine (Cardene, Cardene I.V., Cardene SR), nifedipine (Adalat, Adalat CC, Nifedical XL, Procardia, Procardia XL); combination drug: nifedipine and atenolol (Beta-Adalat, Tenif); nimodipine (Nimotop), nisoldipine (Sular), nitrendipine (Cardif, Nitrepin), verapamil (Calan, Calan SR, Covera-HS, Isoptin, Isoptin SR, Verelan, Verelan PM); combination drug: verapamil and trandolapril (Tarka).

Many studies have demonstrated the value of L-carnitine in the prevention and treatment of cardiovascular disorders. Some clinicians experienced in nutritional therapeutics have suggested that coadministration of carnitine during calcium channel blocker therapy might introduce an additive or synergistic beneficial effect. Evidence from clinical trials is lacking to support this speculation. However, the pharmacological principles underlying this proposal are reasonable and in accordance with known activities and effects of both agents. Research through well-designed clinical trials may be warranted to explore this potential supportive interaction.

Physicians treating individuals with significant risk for or known presence of cardiovascular disease are advised to discuss with their patients the potential benefits of carnitine. L-Carnitine and L-propionyl-carnitine are the forms most often used for prevention and treatment of cardiovascular conditions, with typical therapeutic dosages in the range of 1 to 3 g daily.

Cisplatin, Ifosfamide, and Related Chemotherapy

Cisplatin (*cis*-diaminedichloroplatinum, CDDP; Platinol, Platinol-AQ).

Ifosfamide (Ifex, Mitoxana).

In a preliminary study involving nonanemic cancer patients, Graziano et al.[92] found that concomitant administration of L-carnitine (2 g twice daily) for 7 days relieved chemotherapy-induced fatigue in 90% of subjects who had been treated with cisplatin or ifosfamide. These findings are limited by the lack of a placebo group in the study, which would have enabled accounting for spontaneous resolution of fatigue. Further research through well-designed clinical trials is warranted.

Gentamicin

Gentamicin (G-mycin, Garamycin, Jenamicin).

Based on reports that hearing is improved when L-carnitine is administered to infants with neurological disorders, Kalinec et al.[93] investigated the effectiveness of L-carnitine for preventing the ototoxic effects typically associated with gentamicin therapy. They administered L-carnitine, 100 mg/kg/day, to pregnant guinea pigs beginning either 2 weeks before or simultaneously with gentamicin, 100 mg/kg/day for 7 days. Not only did the administration of L-carnitine prevent neonatal mortality, but it also prevented hearing loss associated with the antibiotic. Thus, using auditory brainstem responses, the authors found that the auditory threshold of untreated offspring was 21 dB, compared with 30 db in those treated with gentamicin but that those treated with L-carnitine starting before or at the same time as gentamicin, demonstrated hearing thresholds restored to 23 db and 21 dB, respectively. Furthermore, confocal microscopy and scanning electron microscopy revealed that L-carnitine ameliorated the significant damage of outer hair cells induced by gentamicin. Further study, using cell culture of an auditory cell line highly sensitive to ototoxic drugs and other biochemical testing, indicated that apoptosis was the mechanism by which gentamicin produced its damaging effects, specifically through upregulation of the Harakiri (Hrk) gene, a proapoptotic member of the Bcl-2 family of proteins, mediated by activation of ERK1/2 and inhibition of the JNK pathways. Their findings suggested that L-carnitine exerted its protective action by preventing inhibition of JNK and the consequent upregulation of Hrk, thus blocking cell death. Based on these findings, these investigators have planned a clinical trial to investigate the ability of L-carnitine to prevent gentamicin-induced ototoxicity.

Propranolol and Related Beta-1-Adrenoceptor Antagonists (Beta-1-Adrenergic Blocking Agents)

Propranolol and Related Beta-1-Adrenoceptor Antagonists (Beta-1 Adrenergic Blocking Agents).

Propranolol (Betachron, Inderal LA, Innopran XL, Inderal)

Related: Acebutolol (Sectral), atenolol (Tenormin), atenolol

combination drugs: atenolol and chlortalidone (Co-Tendione, Tenoretic), atenolol and nifedipine (Beta-Adalat, Tenif), sotalol (Betapace, Betapace AF, Sorine); betaxolol (Kerlone), bisoprolol (Zebeta), carteolol (cartrol), esmolol (Brevibloc), labetalol (Normodyne, Trandate), metoprolol (Lopressor, Toprol XL); combination drug: metoprolol and hydrochlorothiazide (Lopressor HCT), nadolol (Corgard), nebivolol (Nebilet), oxprenolol (Trasicor), penbutolol (Levatol), pindolol (Visken), propranolol combination drug: propranolol and bendrofluazide (Inderex), timolol (Blocadren)

Many studies have demonstrated the value of L-carnitine in the prevention and treatment of cardiovascular disorders. Ferro et al.[94] reported on the case of a 52-year-old man with dilated cardiomyopathy in whom concomitant treatment with L-carnitine and propranolol restored cardiac function, with a 50% reduction in mitral EPSS (E point septal separation), from 20 to 10 mm, and a decrease from 60 to 57 mm in diastolic diameter. These clinicians concluded that their "experience suggests promising benefits in adopting beta blockers combined with L-carnitine therapy in myocardial failure secondary to dilated cardiomyopathy."

After reviewing the literature on the treatment of hypertrophic cardiomyopathy, Ferro et al.[94] also proposed that the protective action of beta-blocking agents against chronic catecholamine stimulation may be enhanced by the combination with L-carnitine. Notably, L-carnitine plays a synergistic role by acting as an important source of energy because of fatty acid oxidation and by avoiding the accumulation of lipids in the blood plasma and myocardium.

Physicians prescribing beta-blocker therapy are advised to discuss with their patients the potential benefits of concomitant carnitine. L-Carnitine and L-propionyl-carnitine are the forms most frequently used for prevention and treatment of cardiovascular conditions, with typical therapeutic dosages in the range of 1 to 3 g per day.

NUTRIENT-NUTRIENT INTERACTIONS

Alpha-Lipoic Acid

Hagen et al.[95] demonstrated improved memory and metabolic function and decreased oxidative stress in old rats fed the combination of acetyl-L-carnitine and lipoic acid.

Coenzyme Q10, Fish Oil, Magnesium, and Taurine

Carnitine, coenzyme Q10, fish oil, magnesium, and taurine are critical nutrients in maintaining healthy cardiovascular function, muscle, and brain tissue and can play a valuable therapeutic role in the treatment of cardiovascular disease and other conditions and the support of CNS function. Health care professionals trained and experienced in nutritional therapies often use multiple nutrients together. These agents are all considered essentially nontoxic. Clinical trials investigating their synergistic effects are clearly warranted.

HERB-NUTRIENT INTERACTIONS

Hawthorn

Hawthorn, *Crataegus laevigata* (Poir) DC., *Crataegus monogyna* Jacq. (Lindm.), *Crataegus oxyacantha L.* (for *C. laevigata*).

Concomitant administration of carnitine and *Crataegus* is common practice among health care professionals trained and experienced in the synergistic use of nutrients and herbs in supporting healthy cardiovascular function and treating cardiovascular conditions. Clinical trials investigating the clinical efficacy of combined therapy using these two agents are lacking, as is research into mechanisms underlying interactions between them. Hawthorn is generally considered essentially nontoxic. Clinical trials investigating their synergistic effects are clearly warranted.

The 95 citations for this monograph, as well as additional reference literature, are located under Carnitine on the CD at the back of the book.

Methionine

Nutrient Name: Methionine.
Synonyms: DL-Methionine, L-methionine.
Related Substance: S-adenosylmethionine (SAM, SAMe; AdoMet).

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Acetaminophen ☼/⊕⊕⊕	Methionine appears to reduce toxic effects of acetaminophen, especially on liver. Long-term, well-designed clinical trials are warranted.	Coadminister, possibly within same dose.
Levodopa (L-dopa) ✗✗/✗✗✗/⊕✗/⊕⊕	Methionine administration (500-1000 mg/day) may benefit individuals with Parkinson's disease, but high doses (> 4 g/day) may interfere with action of levodopa. Multinutrient support is important to protect against elevated homocysteine (Hcy) associated with Parkinson's disease and possibly aggravated by levodopa therapy. Long-term, well-designed clinical trials are warranted.	Consider administration of methionine at low to midrange doses along with folate, B_6, and B_{12}; monitor serum total Hcy. Monitor for interference with levodopa via symptoms.

NUTRIENT DESCRIPTION

Chemistry and Forms

DL-Methionine, L-methionine.

Physiology and Function

Methionine is an essential sulfur-containing amino acid that facilitates and helps initiate the translation of messenger RNA (mRNA) by being the first amino acid incorporated into the N-terminal position of all proteins. The terminal methyl group of the methionine side chain often participates in biochemical methyl transfer reactions, making methionine a member of the "methyl donor" class of biochemicals.

S-adenosylmethionine (SAMe) is intimately involved in the synthesis of brain chemicals and also in detoxification reactions. Methionine is converted into SAMe, which is considered to be the activated form of methionine. This occurs in the first step of the metabolism of methionine, which requires energy in the form of adenosine triphosphate (ATP). In this activation of methionine, an adenosyl moiety is transferred from the ATP molecule. SAMe is one of the most potent methyl donors and is involved in many methylation reactions. Its methyl group, which is attached in a sulfonium linkage with high-energy characteristics, may be donated to any of a large number of methyl-group acceptors in the presence of the appropriate enzyme. DNA methylation influences the expression of many genes and depends on the availability of methyl groups from SAMe. SAMe is intimately involved in the synthesis of neurotransmitters and also in detoxification reactions.

Along with inositol, choline (tetramethylglycine), and betaine (trimethylglycine), methionine is considered a member of the group of compounds called lipotropics that are closely involved in lipid metabolism. Transmethylation metabolic pathways closely interconnect choline, methionine, methyltetrahydrofolate (methyl-THF), and vitamins B_6 and B_{12}. Methionine can be formed from homocysteine using methyl groups from methyl-THF, or using methyl groups from betaine that are derived from choline. Through interrelated pathways, methyl-THF can be formed from one-carbon units derived from serine or from the methyl groups of choline via dimethylglycine, and choline can be synthesized de novo using methyl groups derived from methionine (via SAMe).

Methionine regulates several sulfur-containing compounds in the body that play an important role in liver detoxification processes and the synthesis of structural proteins and enzymes. It acts as a sulfur donor and, as such, is the source of sulfur for biosynthesis of cysteine. Methionine is also the precursor for the synthesis of cystine and taurine and is one of three amino acids required for the synthesis of creatine. Methionine may serve as a precursor for the synthesis of glutathione, which is the substrate for glutathione peroxidase, a crucial antioxidant enzyme. Methionine assists in the metabolism of homocysteine and helps reduce histamine levels.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Methionine is an essential amino acid which is primarily administered to enhance liver functions such as detoxification and lipid metabolism and to support the function of the central nervous system (CNS) and neurotransmitters. In nutritional therapeutics, methionine can be used to increase levels of SAMe, reduced glutathione (GSH), taurine, and *N*-acetylcysteine (NAC) and to promote detoxification of xenobiotics via the sulfation pathway.

Historical/Ethnomedicine Precedent

Not used historically as an isolated nutrient.

Possible Uses

Acrodermatitis enteropathica, AIDS-related dementia, AIDS-related nervous system degeneration, fat maldigestion, human immunodeficiency virus (HIV) support, liver detoxification, migraine headaches, pain control, pancreatitis, Parkinson's disease, radiation effects, schizophrenia, urinary tract infections, weight loss, Wilson's disease.

Deficiency Symptoms

Typical symptoms associated with methionine deficiency include hair loss, hepatic dysfunction, poor skin tone, and toxic elevation of metabolic waste products.

Methionine deficiency is usually related to overall protein malnutrition. Individuals with acquired immunodeficiency syndrome (AIDS) demonstrate low levels of methionine. Experimentally, a methionine deficiency causes premature atherosclerosis in monkeys, especially if they are also deficient in vitamin B_6. Methionine deficiency can also cause a folate deficiency since a deficiency causes 5-methyl-THF to accumulate in the liver. Lower methionine intake during pregnancy has been associated with neural tube defects in newborns.

Dietary Sources

Dairy products, fish, and meat (beef, chicken, pork, liver) are considered the richest dietary sources of methionine. Sunflower seeds, pumpkin seeds, sesame seeds, and lentils are also good sources of methionine. Egg yolks are particularly high in sulfur. Methionine and cysteine make up 91% of the sulfur in the yolk. Endogenous gut flora may be able to synthesize significant amounts. Homocysteine in the diet can eliminate the requirement for methionine.

Soybeans are a poor source, and soy-based infant formulas are generally low in methionine.

Dosage Forms Available

Capsule, powder, tablet; oral and intravenous (IV) administration.

Source Materials for Nutrient Preparations

Most L-methionine in supplements is produced by bacterial fermentation processes in a growth medium, from which the amino acid is then purified. Methionine used in supplements is frequently of the DL form, which implies chemical synthesis, thus resulting in a racemic mixture.

Dosage Range

Adult

Dietary: No reference (recommended) daily intake (RDI) has been established. Average intake in the United States is 2.7 to 5 g per day.
Supplemental/Maintenance: Dietary sources of methionine are usually adequate so supplemental methionine is usually not considered necessary. Optimal levels of intake have not been established but probably are 800 to 1000 mg daily, depending on weight, diet, and related factors.
Pharmacological/Therapeutic: 500 to 3000 mg per day.
Toxic: No toxic dose level has been reported.

Pediatric (< 18 Years)

Dietary: No minimal dietary requirement established.
Supplemental/Maintenance: Not currently recommended for children.
Pharmacological/Therapeutic: Specific treatment recommendations have not established.
Toxic: No toxic dosage level established specifically for infants and children.

Laboratory Values

Serum or Plasma Methionine

Range of normal levels for plasma methionine:
Children: 13 to 30 μmol/L
Adults: 16 to 30 μmol/L

SAFETY PROFILE

Overview

Methionine is usually tolerated well by most adults and generally considered to be free of adverse effects for most individuals at common dosage levels (e.g., 1-3 g/day). Toxicity is rare but possible with excessive dosage. Diets high in methionine may be associated with an increased occurrence of atherosclerosis, especially with concurrent deficiencies of vitamin B_6, vitamin B_{12}, and folic acid, resulting from elevations of blood homocysteine levels.

Nutrient Adverse Effects

General Adverse Effects

Nausea and gastrointestinal (GI) irritation are the primary signs of methionine toxicity, although occurrence is rare. Some sensitive individuals may experience gas, bloating, and digestive discomfort at levels as low as 500 mg per day. Other symptoms reportedly associated with methionine toxicity may include anorexia, ataxia, hyperactivity, reduced growth, hemosiderosis, and suppressed hematocrit. Extremely high doses may increase urinary calcium excretion and could potentially induce hallucinations. However, administration of up to 2 g daily for extended periods has not been associated with any serious adverse effects.

Rats fed methionine as 50% of dietary protein (equivalent human dose of 25 g/day) exhibited hyperactivity, anorexia, reduced growth, and iron accumulation in the spleen.

Pregnancy and Nursing

Evidence is lacking within the scientific literature to suggest or confirm any adverse effects related to fetal development during pregnancy or to infants who are breast-fed associated with methionine administration. Caution still advised.

Infants and Children

No adverse effects have been reported. However, sufficient research-based evidence is lacking to guarantee the safety of methionine in infants and children.

Contraindications

Avoid *S*-adenosylmethionine (SAMe) in Parkinson's disease; administration may aggravate symptoms caused by serotonergic effect.

Precautions and Warnings

Large intakes of methionine require higher intakes of methyl donor–related nutrients, such as B_{12}, folic acid, pyridoxine, choline (tetramethylglycine), betaine (trimethylglycine), and dimethylglycine. Large loads of dietary methionine without concomitant intake of these interdependent nutrients at adequate levels can increase the conversion of methionine to homocysteine (Hcy) and will result in higher levels of Hcy, a vasculotoxic product of intermediary metabolism. Need for methyl donor nutrients in relation to methionine intake varies according to pharmacogenomic determinants, such as methyl-THF reductase enzyme activity. In cases of strong family history of coronary heart disease, it would be judicious to check Hcy levels before and during methionine treatment, because of the potential homocysteinergic and atherogenic effects of methionine.

Animal research conducted by Toborek and Hennig[1] suggests that high dietary intake of methionine, in the presence of

B-vitamin deficiencies, may increase the risk for atherosclerosis by increasing blood levels of cholesterol and Hcy. Troen et al.[2] observed that apolipoprotein E–deficient mice fed methionine-rich diets developed significant atheromatous pathology in the aortic arch, even with normal plasma Hcy levels. These findings suggest that moderate increases in methionine intake are atherogenic in susceptible mice.

Administration may be inappropriate in individuals with osteoporosis because high dosage levels increase urinary excretion of calcium.

INTERACTIONS REVIEW

Strategic Considerations

The issue of methionine function and exogenous administration in individuals with Parkinson's disease and related degenerative neurotransmitter conditions remains unclear, inconclusive, and contentious. Preliminary research by Smythies and Halsey suggests that methionine (5 g/day) may help ameliorate some symptoms of Parkinson's disease. However, some authors have suggested that exogenous methionine, as with other amino acids, may interfere with the absorption or action of the levodopa, particularly in the treatment of individuals with Parkinson's disease. Several studies have reported elevated plasma levels of total Hcy, along with decreased methionine and SAMe, in patients treated long term with levodopa and dopa decarboxylase inhibitors (DDIs) as a result of alterations in levels of substrates of the *O*-methylation cycle.[3]

Several studies have investigated the use of methionine coadministration as a means of reducing toxicity caused by acetaminophen and suggested the probable benefits of such an integrative approach to prescribing.

Viewing methionine administration or supplementation within the larger context of wellness and therapeutics, it is important to note that increasing intake of methionine without providing for adequate intake of folic acid, vitamin B_6, and vitamin B_{12} can augment the conversion of methionine to Hcy and thereby increase cardiovascular risk.

NUTRIENT-DRUG INTERACTIONS

Acetaminophen

Acetaminophen (APAP, paracetamol; Tylenol); combination drugs: acetaminophen and codeine (Capital and Codeine; Phenaphen with Codeine; Tylenol with Codeine); acetaminophen and hydrocodone (Anexsia, Anodynos-DHC, Co-Gesic, Dolacet, DuoCet, Hydrocet, Hydrogesic, Hy-Phen, Lorcet 10/650, Lorcet-HD, Lorcet Plus, Lortab, Margesic H, Medipain 5, Norco, Stagesic, T-Gesic, Vicodin, Vicodin ES, Vicodin HP, Zydone); acetaminophen and oxycodone (Endocet, Percocet 2.5/325, Percocet 5/325, Percocet 7.5/500, Percocet 10/650, Roxicet 5/500, Roxilox, Tylox); acetaminophen and pentazocine (Talacen); acetaminophen and propoxyphene (Darvocet-N, Darvocet-N 100, Pronap-100, Propacet 100, Propoxacet-N, Wygesic); acetaminophen, butalbital, and caffeine (Fioricet).

Effect and Mechanism of Action

Methionine appears to reduce the toxic effects of acetaminophen (paracetamol), particularly on the liver, without adversely affecting (and possibly enhancing) the drug's pharmacokinetics and efficacy. Glutathione is most likely central to such activity, but the mechanisms involved have yet to be fully elucidated. The observed phenomenon might relate to empirical reports of methionine use in liver detoxification; however, the available evidence is not sufficient to support such an extrapolation. Further research is warranted to investigate the mechanisms of action responsible for the observed effects.

Research

Acetaminophen (paracetamol) poisoning is a major source of morbidity and mortality and represents one of the most common examples of adverse drug reactions in conventional medical practice. Numerous studies have demonstrated that coadministration of methionine may be effective in the treatment of acetaminophen toxicity. For more than a decade, various researchers and clinicians have proposed that methionine be incorporated into acetaminophen tablets routinely as a protective mechanism against acetaminophen-induced toxicity.

Skoglund and Skjelbred[4] conducted a randomized, single-blind, between-patient study comparing the onset of analgesia, duration, and efficacy of paracetamol versus a combination medication containing free paracetamol and its *N*-acetylmethionate ester (SUR 2647) in outpatients after oral surgery. Using several subjective and objective assessments, the authors reported that median onset of analgesia for both groups was approximately equivalent (i.e., ≤½ hour) and that the duration of analgesia after the combination was greater than that for paracetamol (i.e., ≥5.5 hours vs. ≥2.5 hours). Furthermore, the combination regimen reduced pain significantly more than the paracetamol from ½ to 3 hours after initiation of medication, but the mean pain scores did not show a significant difference during the remaining observation period. Subjects in both treatment groups reported mild to moderate drowsiness, but it was more common in subjects given the paracetamol/methionine combination.

Research by Neuvonen et al.[5] indicates that methionine might protect against the hepatotoxic effects of acetaminophen. Using a rat model, they compared the analgesic effect, toxicity, and kinetics of oral paracetamol with those of paracetamol + L-methionine (5:1). They reported that the presence of methionine did not significantly change the analgesic effect of paracetamol, but that methionine reduced the acute toxicity (LD_{50}) of paracetamol by 50% in nonfasted, fasted, and phenobarbital-pretreated mice. Subsequently, in a small, randomized crossover study involving 10 human subjects, they observed that coadministration of methionine (300 mg) did not alter the pharmacokinetics of paracetamol (1500 mg). Furthermore, they found that the "absorption of methionine from the combination tablets was rapid, peak concentrations occurred in plasma at 30 min and were 3-4 times higher than after paracetamol tablets not containing methionine."[5] In a later paper, some of these same researchers reviewed their findings and related data and rhetorically asked, "Why not add methionine to paracetamol tablets?"[6]

Based on these concerns and the emerging pattern of evidence supporting coadministration of methionine with acetaminophen, McAuley et al.[7] investigated whether methionine administration might adversely affect cardiovascular risk factors through its effect on endothelial function, plasma homocysteine (Hcy), and lipid peroxidation in 16 healthy volunteers. Their findings showed no significant difference in

endothelial-dependent vascular responses after acute (250 mg orally), 1 month of low-dose (250 mg daily), or 1 week of high-dose (100 mg/kg daily) methionine. Plasma Hcy concentrations demonstrated no significant differences after acute or 1 month of low-dose methionine. However, Hcy concentrations significantly increased after 1 week of high-dose methionine (100 mg/kg) daily. Thus, methionine administration at dosage levels similar to those used in combination preparations with acetaminophen do not adversely affect plasma Hcy concentrations. The observation that high-dose methionine administration can cause elevated plasma Hcy concentrations in only 1 week is consistent with other research findings on methionine administration outside the context of synergistic nutrients.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Pending release of a commercial product combining acetaminophen and methionine, health care professionals are advised that it is reasonable to coadminister the two agents, particularly for patients who take acetaminophen on a long-term basis, such as for osteoarthritis. Although definitive conclusions from large, well-designed, controlled, double-blind clinical trials is lacking at this time, the evidence thus far available strongly indicates a pattern of clinical efficacy and lack of adverse effects associated with such coordinated use. Monitoring of Hcy would be judicious with long-term use in at-risk patients.

Levodopa

Levodopa (L-dopa; Dopar, Larodopa); combination drugs: levodopa and benserazide (co-beneldopa; Madopar); levodopa and carbidopa (Atamet, Parcopa, Sinemet, Sinemet CR); levodopa, carbidopa, and entacapone (Stalevo).

Effect and Mechanism of Action

Depletion of dopamine in the striatum of the brain plays a central role in the symptoms of Parkinson's disease. As a dopamine precursor, levodopa is able to cross the blood-brain barrier (BBB) to enter the CNS. After being decarboxylated to dopamine in the basal ganglia, L-dopa is able to replenish depleted dopamine stores and provide symptomatic relief. Methionine may diminish the therapeutic effect of levodopa through a mechanism that has not yet been elucidated but likely to involve *S*-adenosylmethionine, a methyl-activated metabolite of methionine.

Amino acids (in high-protein foods or as supplements) may compete with levodopa for transport across the BBB and thereby interfere with the drug's therapeutic activity.[8]

S-adenosylmethionine (SAMe) is a key metabolic contributor to the recycling of Hcy. Methylation of multiple intracellular molecules, including nucleic acids and proteins, uses SAMe as the donor, which is converted to *S*-adenosylhomocysteine (SAH), which in turn is in equilibrium with Hcy. The regeneration of methionine, the precursor of SAMe, occurs in neurons exclusively through methionine synthase, which requires methyl-THF azad vitamin B_{12}. Additionally, vitamin B_6 deficiency results in total-Hcy elevation by preventing the conversion by cystathionine synthase of Hcy to cystathionine.

Research

The use of methionine in patients with Parkinson's disease potentially presents both problems and opportunities as a component of an integrative therapeutic strategy and when used concomitantly with levodopa. Administration of L-methionine may benefit individuals with Parkinson's disease.[9,10] However, the available evidence is preliminary, contradictory, and unclear. In a preliminary clinical trial involving 15 patients who had obtained maximal improvement from L-dopa, carbidopa-levodopa, and/or anticholinergic compounds, Smythies and Halsey[10] found that 10 exhibited improvement on all measures except tremor and drooling when administered methionine (500 mg with 25 mg pyridoxine), starting at 1 g daily and gradually increasing to 5 g daily over 3 weeks. The authors cautioned that such nutrient therapy "should be avoided by patients on L-dopa or Sinemet." In a randomized, double-blind clinical trial lasting 8 days, Pearce and Waterbury[11] administered 4.5 g methionine daily or placebo to 14 Parkinson's patients who were clinically stable after at least 3 months of levodopa therapy (1.5-5.5 g/day); all subjects were restricted to 0.5 g/day dietary methionine. Concomitant methionine decreased the therapeutic effects of levodopa and exacerbated related symptoms, such as gait disturbances, increased tremor, and rigidity. The adverse effects disappeared when methionine was discontinued, although one patient declined to a state worse than at the study onset and required 7 to 10 days to recover fully. These preliminary findings suggest that high dosage levels of methionine (≥ 4.5 g/day) may interfere with the therapeutic effects of levodopa, whereas lower doses may be compatible. The short duration of these studies limits the ability to extrapolate these findings over a longer period because of inability to assess whether symptoms would continue to worsen or might be modified by physiological adaptation over time.

In a clinical trial involving six children with dopamine deficiency, Surtees and Hyland[12] demonstrated that elevating levodopa concentrations in the CNS caused a fall in cerebrospinal fluid (CSF) SAMe concentration and a rise in CSF 3-methoxytyrosine concentration. No change was observed in CSF methionine concentration, and all patients had normal CSF 5-methyl-THF concentration. These findings suggest that levodopa depletes SAMe in the CNS and may also disrupt the homeostatic regulation of Hcy.

Parkinson's patients treated with levodopa often develop elevated plasma Hcy.[13-16] Levodopa metabolism via catechol-*O*-methyltransferase increases levels of the neurotoxin Hcy, which induces an axonal-accentuated degeneration in sensory peripheral nerves in vitro.[16] This pattern of drug-related elevation in plasma Hcy suggests at least one major factor in developing an understanding of the increased mortality caused by vascular disease in individuals diagnosed with Parkinson's disease.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The available evidence can be reasonably interpreted to suggest that physicians treating individuals with Parkinson's disease consider prescribing methionine at doses of 500 to 1000 mg daily, i.e., within the common range, for its possible benefits

without introducing significant risk of interfering with the therapeutic activity of levodopa (or levodopa/carbidopa). In cases where methionine administration may be indicated, it is essential to monitor for reduced therapeutic effect of levodopa given the potential that methionine may inhibit levodopa's antiparkinsonian effects, especially at doses of 4.5 g/day or higher. In the event of an adverse interaction, the severity is generally moderate; the rate of onset is unknown. Given the well-established risk of elevated Hcy in such cases, health care professionals treating individuals with Parkinson's disease receiving levodopa therapy are advised to coadminister folate and vitamin B_{12}, both of which help recycle Hcy, as well as monitor fasting plasma Hcy levels.

Furthermore, concomitant tyrosine, phenylalanine, and tryptophan should be considered because levodopa can interfere with absorption of these three amino acids, thereby inducing deficiency. Notably, L-tyrosine is a direct precursor to levodopa. However, although concomitant therapy with L-tyrosine, L-phenylalanine, and L-tryptophan may be beneficial, intake needs to be separated from L-dopa by at least 2 hours because these amino acids can compete with L-dopa for absorption.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Vidarabine

Evidence: Vidarabine (Ara-A, arabinoside; Vira-A).
Similar properties but evidence lacking for extrapolation: Related nucleoside antivirals.

The most common use of vidarabine is as an ophthalmic preparation for the treatment of herpes simplex virus type 1 (HSV-1) and type 2 (HSV-2) in acute keratoconjunctivitis and recurrent superficial keratitis. The therapeutic action of vidarabine is achieved by interfering with viral DNA synthesis, specifically inhibition of *S*-adenosylhomocysteine hydrolase (SAH), methionine synthesis, and SAMe-dependent DNA methylation.[17-19] Vidarabine cannot be given orally because it is metabolized in the gut, so it is usually administered intravenously or topically.

The action of vidarabine indicates a potential risk for interfering with methionine function in humans and potentially inducing a depletion of methionine with extended use. Any such depleting effect on methionine status is likely to be gradual and cumulative, but evidence from human trials is lacking. Concomitant administration of methionine (or SAMe) could theoretically interfere with the therapeutic activity of vidarabine or related antiviral medications.

It has long been established that vidarabine is known to interfere with methionine synthesis, although recent and substantial research is lacking.[17,18] Human studies are lacking to determine whether vidarabine might induce clinically significant methionine depletion or whether methionine administration might interfere with the medication's antiviral activity. Further research is warranted.

Physicians prescribing vidarabine for an extended period are advised to discuss options for countering the potential adverse effects of this medication. Some nutritionally oriented physicians have found value in monitoring serum methionine in their patients taking vidarabine. Close monitoring is warranted in cases where methionine administration is indicated so as to prevent potential reduction of drug efficacy.

NUTRIENT-NUTRIENT INTERACTIONS

Antioxidants

As with other antioxidants, methionine may work synergistically to produce an antioxidant network effect. In a small but well-controlled trial, Uden et al.[20] found that 2 g/day methionine in combination with several antioxidants reduced pain and recurrent attacks of pancreatitis in patients with chronic recurring pancreatitis. In a 20-week, double-blind, double-dummy crossover trial, these researchers provided treatment as two types of tablets containing daily doses of 600 µg organic selenium, 9000 IU beta-carotene, 0.54 g vitamin C, 270 IU vitamin E, and 2 g methionine. Of the 20 patients who adhered to the full protocol, six experienced an attack while on the placebo phase of the crossover trial, compared with none while on the active-treatment phase. Despite the small number of patients in the trial, these results were statistically significant in favor of the antioxidant phase, indicating that this is a large effect. Larger trials would be warranted for this difficult-to-manage clinical problem.

Folate, Vitamin B_6, and Vitamin B_{12}

Methionine works synergistically with folate, vitamin B_6, and vitamin B_{12} in the management of homocysteine (Hcy) and in regulating the relationships and facilitating the functions of these interconnected nutrients.

Animal studies suggest that, in the presence of B-vitamin deficiencies, high dietary intake of methionine may produce hypercholesterolemia and hyperhomocysteinemia, thereby elevating risk for atherosclerosis.[1] These observations have not been directly confirmed by human trials. However, McAuley et al.[7] found that 7 g methionine daily (i.e., megadoses) can elevate blood levels of Hcy in the absence of a deficiency of folic acid, B_6, or B_{12}.

Carmel et al.[21] studied Hcy metabolism in 22 patients with pernicious anemia (vitamin B_{12} deficiency). They found that only levels of total Hcy and cysteine were increased and only glutathione (glutamyl-cysteinyl-glycine) was decreased in cobalamin deficiency as a whole, compared with 17 control subjects. SAMe levels correlated only with methionine levels and cysteine levels only with cysteinylglycine in healthy subjects, but in cobalamin-deficient patients, SAMe correlated instead with cysteine, cysteinylglycine, and folate levels only. Significant differences appeared in clinically subgrouped cobalamin-deficient patients. The 11 B_{12}-deficient patients with neurological damage had higher mean levels of folate, SAMe, cysteine, and cysteinylglycine than did the 11 neurologically unaffected, B_{12}-deficient patients. In all patients, cobalamin therapy restored metabolic changes to normal.

The 21 citations for this monograph, as well as additional reference literature, are located under Methionine on the CD at the back of the book.

Phenylalanine

Nutrient Name: Phenylalanine.
Synonyms: DL-Phenylalanine (DLPA), D-phenylalanine (DPA), L-phenylalanine (LPA).
Related Substances: Tyrosine, aspartame.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Baclofen ◇◇	Baclofen intestinal transport is mediated, at least in part, by beta-, gamma-, and alpha-amino acid carriers and may be reduced by phenylalanine. Clinical significance uncertain.	Avoid simultaneous intake of baclofen with phenylalanine or even with high-protein meal.
Levodopa (L-dopa) ✗✗/◇◇/⊕✗/⊕	Levodopa and phenylalanine (alone or in high-protein foods) may compete for CNS transport when taken concomitantly and thereby reduce drug activity. Conversely, phenylalanine is precursor of L-tyrosine and thus L-dopa. Relative influence of countervailing factors may depend on baseline values, timing of administration, and other factors. Clinical significance uncertain. Long-term, well-designed clinical trials are warranted.	Coadministration, possibly with intake separated by several hours, may be beneficial with proper monitoring and management.
Methadone, morphine Oral narcotic analgesics, opiates ✗/⊕✗/⊕⊕	D-Phenylalanine (DPA) may increase circulating enkephalin levels by inhibiting breakdown of enkephalinase. Coadministration may enhance analgesic effect by this mechanism and by direct analgesic action of DPA. Adverse effects improbable. Well-designed clinical trials are warranted to investigate coadministration in treatment of chronic pain.	Coadministration may be beneficial with close monitoring and active management.
Naloxone ◇/✗✗/⊕✗	Naloxone may inhibit D-phenylalanine's analgesic effect.	Avoid concomitant use. Consider alternate options to phenylalanine for analgesia if naloxone is necessary.
Phenothiazine Butyrophenone neuroleptics Typical antipsychotics ✗✗✗	Exogenous phenylalanine could theoretically elevate levels of dopamine and other tyrosine-derived neurotransmitters. Concomitant administration with neuroleptics might increase risk of drug-induced tardive dyskinesia.	Avoid concomitant intake. Monitor closely if both agents determined to be appropriate and necessary.
Selegiline Monoamine oxidase (MAO-B) inhibitors ✗/⊕✗/⊕⊕	D-Phenylalanine (or LPA) can be converted to phenylethylamine and contribute to enhanced response when used concomitantly with selegiline. L-Phenylalanine (or DPA) could theoretically be converted to L-tyrosine and induce excessive levels of tyrosine and dopamine in presence of MAO-B inhibitor. Adverse effects improbable. Well-designed clinical trials are warranted to investigate safety and efficacy of coadministration.	Coadministration of DPA or DLPA may be beneficial with close monitoring and active management. MAO-B inhibitor dosage may need to be reduced.

CNS: Central nervous system.

NUTRIENT DESCRIPTION

Chemistry and Forms

L-Phenylalanine and DL-phenylalanine (DLPA) are the commercially available forms of phenylalanine. However, phenylalanine appears in the following three chemical forms:

- L-Phenylalanine, the form of phenylalanine that occurs naturally in proteins within the human body.
- D-Phenylalanine, a synthetic mirror image of L-phenylalanine.
- DL-Phenylalanine, a synthesized racemic mixture of L-phenylalanine and D-phenylalanine.

Physiology and Function

L-Phenylalanine is an essential amino acid that serves as a precursor in the biosynthesis of other amino acids including L-tyrosine. It plays a critical role in related biochemical processes involving the synthesis of several important neurotransmitters, principally L-dopa, dopamine, epinephrine, and norepinephrine, as well as thyroxine and melanin. Through a different metabolic pathway, L-phenylalanine can also be converted to phenylethylamine (PEA). Phenylethylamine is a naturally occurring substance in the brain that appears to exert stimulant effects and elevate mood. It also influences the synthesis of many important brain neuropeptides, including vasopressin, adrenocorticotropic hormone (ACTH), somatostatin, enkephalin, and angiotensin II. Together with tryptophan, phenylalanine governs the release of the intestinal hormone cholecystokinin (CCK).

Hepatic conversion of phenylalanine to tyrosine can be impaired during infection, trauma, chronic illness, liver disease, or other forms of severe stress; thus making tyrosine a conditionally essential amino acid.

Because D-phenylalanine does not occur naturally, it cannot be converted to L-tyrosine, L-dopa, or norepinephrine and, when ingested, is primarily converted to phenylethylamine. D-Phenylalanine can increase levels of enkephalins by blocking enkephalinase, thereby inhibiting the breakdown of these opiate-like substances in the brain. This analgesic effect of D-phenylalanine is inhibited by naloxone.

DL-Phenylalanine does not occur naturally in the human body.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Therapeutically, phenylalanine is primarily known for its proposed antidepressant and analgesic effects. Thus far clinical trials of various design, power and clinical relevance have

resulted in mixed results. DLPA should be taken only under medical supervision because of its strong effects on neurotransmitters, mood, and central nervous system (CNS) function. It is generally recommended that phenylalanine be taken 15 to 30 minutes before meals to avoid competition from protein-derived amino acids.

Historical/Ethnomedicine Precedent

Phenylalanine has not been used historically as an isolated nutrient.

Possible Uses

Clinical application varies according to form.

L-Phenylalanine: Appetite suppression, depression, vitiligo.
D-Phenylalanine: Depression, osteoarthritis, Parkinson's disease, rheumatoid arthritis, and pain from a variety of causes, such as chronic back pain, dental pain, menstrual cramps, and migraines.
DLPA: Alcohol withdrawal, depression, osteoarthritis, rheumatoid arthritis, and pain from a variety of causes (from action of D-phenylalanine).

Deficiency Symptoms

Frank phenylalanine deficiency is considered a very uncommon occurrence, and the potential for deficiency is primarily associated with very low protein intake. Typical symptoms of phenylalanine deficiency include fatigue, confusion, behavioral changes, decreased alertness, impaired memory, poor vascular health, eye disorders (e.g., bloodshot eyes, cataracts), changes in appetite, and weight gain.

Dietary Sources

Cheese and meats are the richest dietary sources of phenylalanine, with most protein-containing foods providing some L-phenylalanine, for example, beef, poultry, pork, fish, milk, yogurt, cheese, eggs, soy products (including tofu, soy flour, and soy protein isolate), and certain nuts and seeds.

D-Phenylalanine does not naturally occur in foods.

Aspartame (L-aspartyl-L-phenylalanine methyl ester) is a synthesized dipeptide, composed of aspartic acid and phenylalanine as the methyl ester. It is marketed as an ingredient in food products as NutraSweet and as an artificial sweetener (Equal).

Nutrient Preparations Available

Phenylalanine should generally be administered in the L-phenylalanine form, the naturally occurring isomer, as the preferred form in the treatment of all conditions other than pain and depression. In the treatment of these conditions, particularly chronic pain, D-phenylalanine exhibits unique activity in the CNS/brain and thus makes a critical contribution as part of DLPA. Thus, many health care professionals trained and experienced in nutritional therapeutics might suggest that DLPA is perhaps the only amino acid where the racemic mix is often clinically effective, or even preferable, in contrast to most amino acids, where the naturally occurring L-isomer is strongly if not exclusively recommended.

Dosage Forms Available

Capsule, powder, tablet, topical cream.

Source Materials for Nutrient Preparations

L-Phenylalanine is commercially produced by a bacterial fermentation process. DLPA and D-phenylalanine are synthesized.

Dosage Range

Adult

Dietary: Recommended dietary allowance (RDA): 14 mg per kg body weight per day, or about 1 g for a 70-kg adult.
Supplemental/Maintenance: Usually not necessary. Optimal levels of intake have not been established.
Pharmacological/Therapeutic: L-Phenylalanine is usually provided in doses of 500 mg, typically taken one to three times daily, preferably between meals. Doses of 100 to 200 mg daily are often used in the treatment of depression. The dosage range in most cases is 750 to 3000 mg daily for adults. Doses as high as 50 to 100 mg/kg have been used in studies of those with *vitiligo*, an autoimmune process in which melanocytes are destroyed, resulting in patches of depigmented skin.

DL-Phenylalanine (DLPA) is the most common form of phenylalanine used as a nutraceutical, typically in dosages ranging from 75 mg to 1500 mg daily. DLPA is 50% D-phenylalanine and 50% L-phenylalanine and generally comes in capsules containing 375 to 750 mg. One to two capsules are usually taken in the morning on waking, preferably on an empty stomach. Doses used in research on pain relief were 4 g before an acute painful episode, such as surgery, or 500 mg three times daily for chronic pain.
Toxic: The maximum safe dosage level of phenylalanine, in any form, has not been established. Doses in excess of 1500 mg/day may produce adverse effects.
Experienced practitioners of nutritional medicine generally caution that dosages of various forms of phenylalanine should never exceed 2400 mg/day. Concern has also been raised that prolonged use of any D-isomer amino acid may eventually exert a toxic effect.

Pediatric (< 18 Years)

Dietary: RDA (recommended dietary allowances):

Birth to 4 months: 125 mg/kg/day
5 months to 2 years: 69 mg/kg/day
3 to 12 years: 22 mg/kg/day
Adolescents, 14 to 18 years: 14 mg/kg/day

Supplemental/Maintenance: Not currently recommended for children.
Pharmacological/Therapeutic: Specific treatment recommendations have not established.
Toxic: No toxic dosage level established specifically for infants and children.

Laboratory Values

Serum or Plasma Phenylalanine

Range of normal levels for plasma phenylalanine:

Children: 26 to 86 μmol/L
Adults: 41 to 68 μmol/L

SAFETY PROFILE

Overview

L-Phenylalanine and DLPA are generally considered safe in most individuals at usual dosage levels. Some sources caution that DLPA should be taken only under medical supervision because of its potentially strong effects on neurotransmitters, mood, and CNS function. Although no serious adverse effects have been reported in humans taking phenylalanine, dosage levels greater than 1500 mg/day should be supervised by a health care professional trained and experienced in nutritional therapeutics.

Nutrient Adverse Effects

General Adverse Effects (Adults)

L-Phenylalanine. Animal studies have reported toxicity symptoms at dosage levels of 100 mg/kg or more. Burkhart and Burkhart,[1] two leading phenylalanine researchers, have expressed concerns about potential toxicity with high-dosage administration in humans.

DL-Phenylalanine. The maximum safe dosage level of DLPA is unknown. Within clinical trials 1500 mg/day or less of DLPA has not induced consistent toxicity in healthy subjects. Some researchers and clinicians have reported occasional anxiety, nausea, dyspepsia, and transient headaches. Cautions regarding LPA are most likely equally applicable to DLPA.

Adverse Effects Among Specific Populations

Phenylketonuria. Phenylketonuria (PKU) is an inherited error of metabolism caused by a deficiency in the enzyme phenylalanine hydroxylase (PAH; phenylalanine 4-monoxygenase). PAH utilizes tetrahydrobiopterin to convert phenylalanine into tyrosine, a critical step in dopamine biosynthesis. Loss of this enzyme results in mental retardation, organ damage, and unusual posture and in cases of maternal PKU, can severely compromise pregnancy as a result of the accumulation of phenylalanine and its neurotoxic metabolites. Classic PKU is an autosomal recessive disorder, caused by mutations in both alleles of the gene for PAH, found on chromosome 12. Mild hyperphenylalaninemia (phenylketonuria II) is a phenotypically mild form of PKU that will predominate when the individual is heterozygous for the two mutations of PAH.

In the United States, standards of practice mandate that newborns be tested for PKU during the initial 48 to 72 hours after delivery. If not diagnosed and treated before 3 weeks of age, PKU can cause severe, irreversible mental retardation.

Prudence suggests that high blood levels of phenylalanine (and tyrosine) be avoided in individuals with severe liver disease; such elevation may contribute to encephalopathy, mental impairment, and coma.

Pregnancy and Nursing

Phenylalanine is generally contraindicated because of potential adverse effects on the fetus.

Evidence is lacking in the scientific literature to suggest or confirm any adverse effects related to fetal development during pregnancy or to infants who are breast-fed associated with phenylalanine administration.

Infants and Children

Testing for PKU is critical before any administration. Otherwise, no adverse effects have been reported. However, sufficient research-based evidence is lacking to guarantee the safety of phenylalanine in infants and children.

Contraindications

Phenylalanine should not be taken by phenylketonuric individuals because they lack the enzyme necessary to metabolize phenylalanine.

Exogenous phenylalanine is generally considered contraindicated during pregnancy or while nursing.

Phenylalanine should be used with caution by people with hypertension; it may raise blood pressure in some individuals.

Phenylalanine (and tyrosine) should be avoided by individuals with cancer, especially pigmented melanoma.

Use of phenylalanine may be contraindicated for individuals with hyperthyroidism or schizophrenia, particularly when high dopamine levels are present in the brain. Exogenous phenylalanine (or tyrosine) administration could theoretically result in elevated brain dopamine levels and symptom aggravation.

Precautions and Warnings

L-Phenylalanine should not be taken with foods high in protein because it competes with other amino acids for a position on the same amino acid carrier.

Avoid concomitant administration of phenylalanine and tyrosine because of potential additive effects.

Some derivative sources suggest that phenylalanine should be avoided by individuals taking monoamine oxidase (MAO) inhibitors, presumably because of L-phenylalanine's role in synthesis of dopamine, norepinephrine, and epinephrine. However, this potential for an adverse interaction has not been substantiated by clinical studies; in fact, some research points to synergistic value of such a combination at appropriate dosage levels.

The use of phenylalanine-containing aspartame by individuals with Parkinson's disease is the subject of ongoing controversy. Ingestion of aspartame, the artificial sweetener, may induce a rapid increase in brain levels of phenylalanine. Aspartame is generally contraindicated in individuals with phenylketonuria (PKU). Statements implying that aspartame is "safe" in Parkinson's disease patients derive solely from a single-day, poorly designed study by Karstaedt and Pincus[2] involving 16 levodopa-treated patients with Parkinson's disease. Some clinicians and researchers have suggested that aspartame may be contraindicated in such individuals because of potential for rapid elevation of phenylalanine and effect on levodopa levels. Long-term, independent clinical trials are lacking.

INTERACTIONS REVIEW

Strategic Considerations

Management of *chronic pain* may constitute the most common use of phenylalanine in conventional medicine and the professional practice of natural therapeutics. Several trials of varying design quality, size, and power have been conducted with mixed findings.[3,4] Two preliminary studies suggest possible analgesic action of D-phenylalanine.[5,6] In contrast, Walsh and other researchers at the University of Texas published two critical articles. They noted potentially flawed design in a letter challenging the hypothesis of D-phenylalanine analgesic action via mediation of opiate receptors.[7] In a double-blind trial, they reported that using D-phenylalanine (250 mg four times daily) for 4 weeks was no more effective than placebo for 30 people with various types of chronic pain, including 13 individuals with low back pain.[8] That use of phenylalanine

as pharmacological monotherapy is not representative of its application by health care professionals trained and experienced in nutritional therapeutics.

In a small, two-part, placebo-controlled clinical trial more relevant to typical integrative approaches, Kitade et al.[9] hypothesized that D-phenylalanine (DPA) might prolong analgesia induced by acupuncture through its known activity of blocking carboxypeptidase, an enzyme that degrades enkephalins (endogenous neuropeptides that bind to opiate receptors in the CNS). This team of Japanese researchers administered DPA (4 g/day) to individuals with chronic low back pain half an hour before they received acupuncture. The results were good or excellent for 18 of the 30, but not statistically significant because of small sample size. These researchers arrived at a similar conclusion when tooth extraction was performed on 56 patients under acupuncture anesthesia, with 18 subjects receiving 4.0 g DPA orally 30 minutes before treatment and 38 given placebo. These researchers also found that the combined DPA-acupuncture effect was slightly better when DPA was given on the previous day in three 0.5-g doses than a single 4-g dose administered 30 minutes before treatment.

The coadministration of DPA and conventional analgesics represents an integrative approach to care that warrants further research. DL-Phenylalanine (DLPA) is the most common form of phenylalanine administered for pain relief by health care professionals, at a typical dose of 1500 to 2500 mg per day. Further research employing placebo-controlled double-blind pain studies, as well as outcomes-based research for assessing multidisciplinary interventions, is warranted to evaluate the efficacy of phenylalanine in the treatment of pain syndromes and to determine dosage levels, synergies, and other aspects of therapeutic protocols for its effective integration into clinical care models.

Although not conclusively established by large, well-designed human trials, a solid theoretical foundation, broad anecdotal reports, and numerous preliminary studies suggest therapeutic benefit in using phenylalanine as part of a comprehensive therapy for depression. Administration of L- or DL-phenylalanine alone, with other nutrients, or with conventional medications and psychotherapy, can support healthy neurotransmitter levels by enhancing production of dopamine and norepinephrine. Health care professionals treating individuals diagnosed with depression are advised to query patients about self-medication; present evidence-based options for integrative therapies employing exercise, dietary changes, nutrient coadministration, botanical medicine, acupuncture, stress resilience training, and other appropriate therapies; and offer support in the form of supervision, monitoring, and collaboration with other health care providers.

Tardive dyskinesia (TD), a condition characterized by unusual, uncontrollable body movements, was first brought to the attention of the medical community in 1973 by Crane.[10] Since then, clinicians and researchers have studied this largely irreversible and untreatable neurological disorder in patients receiving long-term neuroleptic agents. In 1992 the American Psychiatric Association estimated that TD occurs in at least 5% of patients taking certain antipsychotic medications annually. Within 3 years, 15% of these patients develop TD, and its prevalence often exceeds 50% of all patients in long-term antipsychotic medication studies. The disease affects children and adults of all ages, with higher rates among older populations. In a controlled study, Yassa et al.[11] found that 41% of patients age 65 and older developed TD within 24 months. It is estimated that TD could affect as many as 1 million Americans. Concomitant use of conventional antipsychotic medications and phenylalanine, a dopamine precursor, could theoretically increase the risk of developing neuroleptic-induced TD by elevating levels of dopamine, norepinephrine, and epinephrine. Phenylalanine supplementation, particularly when self-prescribed and unmonitored, should generally be avoided by individuals under treatment with antipsychotic agents, including phenothiazine and butyrophenone types and newer, atypical antipsychotic agents. In clinical trials, vitamin E has reduced the severity of TD, especially involuntary movements.[12,13] In a double-blind, placebo-controlled, crossover study, Lerner et al.[14] observed that coadministration of vitamin B_6 can control TD. Concomitant choline and lecithin may also reduce TD symptoms. Nutritional support can be therapeutically efficacious when appropriate to the individual being treated, strategically planned, and applied with monitoring within an integrative therapeutic framework.

The role of amino acid intake and therapeutics within integrative approaches to oncology is not well researched. Increased expression of various tyrosine kinase enzymes is key to growth and cell signaling in a wide variety of tumor types. A low-phenylalanine and low-tyrosine diet has shown some potential in limiting tumor growth in animal models. However, Harvie et al.[15] found that patients with advanced cancer do not appear to tolerate or accept such a diet. In a small pilot study involving 22 patients with advanced metastatic melanoma and 15 patients with metastatic breast cancer, the diet was restricted to 10 mg/kg/day each of phenylalanine and tyrosine in foods or supplements. Only three patients with metastatic melanoma and three with metastatic breast cancer agreed to start the diet. After 1 month, these researchers attempted to establish the effect of the diet on nutritional status; immune cell function; plasma levels of phenylalanine, tyrosine, and tryptophan; and quality of life, as measured by Hospital Anxiety and Depression scores. All the patients who followed the restricted diet reported adverse effects, particularly increases in anxiety and depression. Although slight increases in white cell counts and neutrophils were observed, patients on the diet also experienced declines in weight, with loss of fat and fat-free mass.

NUTRIENT-DRUG INTERACTIONS

Baclofen

Baclofen (Kemstro, Lioresal).

Interaction Type and Significance

◇◇ **Impaired Drug Absorption and Bioavailability, Precautions Appropriate**

Probability:
4. Plausible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Baclofen is a skeletal muscle relaxant medicine that works by binding to gamma-aminobutyric acid type B (GABA-B) receptors in the CNS. Phenylalanine may reduce absorption of baclofen.

Research

In a series of experiments examining inhibition of baclofen absorption by beta-alanine, GABA, and leucine, a group of Spanish researchers found that baclofen intestinal transport was mediated, at least in part, by the beta-, gamma-, and

alpha-amino acid carriers.[16-21] Cejudo-Ferragud et al.[22] found that phenylalanine (up to 100 mM) decreased the absorption of isotonic perfusion solutions of baclofen (0.5 mM) by 67% in situ in rat small intestines.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing baclofen should advise patients to avoid intake of phenylalanine or even a meal high in protein content 2 hours before or 4 hours after medication to prevent impaired drug absorption.

Levodopa

Levodopa (L-dopa; Dopar, Larodopa); combination drugs: levodopa and benserazide (co-beneldopa; Madopar); levodopa and carbidopa (Atamet, Parcopa, Sinemet, Sinemet CR); levodopa, carbidopa, and entacapone (Stalevo).

Interaction Type and Significance

- ✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**
- ◈◈ **Impaired Drug Absorption and Bioavailability, Precautions Appropriate**
- ⊕✗ **Bimodal or Variable Interaction, with Professional Management**
- ⊕ **Potential or Theoretical Beneficial or Supportive Interaction, With Professional Management**

Probability: **4. Plausible**

Evidence Base: **○ Preliminary**

Effect and Mechanism of Action

Concomitant intake of amino acids as supplements or high-protein food may result in competition within CNS transport systems between levodopa and these nutrients, including phenylalanine.[23] Because phenylalanine is a precursor of L-tyrosine, a semi-essential amino acid that converts to L-dopa, an additive effect may occur with coadministration. The relative effect of these two influences has not been established and could be significantly altered by other variables, such as patient characteristics, baseline levels, and substance intake.

Research

High intake and elevated blood levels of amino acids, especially hyperphenylalaninemia, could induce blockade of the therapeutic effects of levodopa. In animal experiments, Wade and Katzman[24] observed that the large, neutral amino acid phenylalanine and L-dopa share a transport system into the brain. Consequently, researchers and clinicians assume that L-dopa levels in the brain would be inversely related to plasma neutral amino acid levels. In subsequent research, Nutt, Woodward, et al.[25] attributed the oscillating clinical response (the "on-off" phenomenon) seen in Parkinson's patients receiving L-dopa therapy to interference with absorption of levodopa by dietary amino acids and competition between large, neutral amino acids and levodopa for transport from plasma into the brain. They report that "bypassing absorption by constant infusion of the drug produced a stable clinical state lasting for twelve hours in all of six patients and for up to 36 hours in some. High-protein meals or oral phenylalanine, leucine, or isoleucine (100 mg per kilogram of body weight) reversed the therapeutic effect of infused levodopa without reducing plasma levodopa concentrations. Glycine and lysine at identical doses had no effect." In a subsequent clinical trial, these researchers[26] monitored the motor response and plasma and ventricular cerebrospinal fluid (CSF) concentrations of L-dopa during intravenous (IV) infusions of L-dopa in two patients with advanced Parkinson's disease. They first observed that concentrations of L-dopa in ventricular CSF mirrored, but lagged behind, those in plasma. Then, during IV infusions of L-dopa following oral administration of phenylalanine, they noted that the duration of the motor response was greatly attenuated despite undiminished ventricular CSF levels of L-dopa. These researchers interpreted these findings to suggest that either L-dopa entry into ventricular CSF and the brain are "differentially affected by phenylalanine or that phenylalanine affects other steps in the motor response."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing levodopa are advised to be aware of the possible responses to phenylalanine intake and their potential clinical implications. On the one hand, increased intake of phenylalanine (or L-tyrosine) might augment L-dopa levels. This potential additive response could be beneficial or detrimental depending on resultant levels, patient response, and clinical management. On the other hand, the simultaneous ingestion of phenylalanine and related amino acids, especially leucine and isoleucine, could interfere with levodopa pharmacokinetics and diminish its therapeutic effects.

The use of phenylalanine (or tyrosine) along with levodopa may represent a valuable integrative approach to the treatment of individuals with Parkinson's disease. Close monitoring of L-dopa levels is essential in cases where a therapeutic trial of such coadministration appears appropriate. Furthermore, administration of the two amino acids should be separated by at least 2 hours before or 4 hours after the medication to minimize risk of interference with absorption and transport and enhance endogenous L-dopa synthesis. Further research with well-designed, long-term clinical trials is warranted.

Methadone, Morphine, and Related Oral Narcotic Analgesics (Opiates)

Butorphanol (Stadol, Stadol NS), codeine sulfate, fentanyl (Actiq Oral Transmucosal, Duragesic Transdermal, Fentanyl Oralet, Sublimaze Injection), hydrocodone, hydromorphone (Dilaudid), levorphanol (Levo-Dromoran), meperidine (Demerol), methadone (Dolophine, Methadose), methadone hydrochloride (Dolophine, Methadose), morphine sulfate (Astramorph PF, Avinza, Duramorph, Infumorph, Kadian, MS Contin, MSIR, Oramorph SR, RMS, Roxanol, Roxanol Rescudose, Roxanol T), opium tincture, oxycodone (Endocodone, OxyContin, OxyIR, Percolone, Roxicodone), oxymorphone (Numorphan), paregoric, pentazocine (Talwin, Talwin NX), propoxyphene (Darvon; Darvon-N).

Combination drugs: Buprenorphine and naloxone (Suboxone); codeine and acetaminophen (Capital and Codeine; Phenaphen with Codeine; Tylenol with Codeine); codeine and acetylsalicylic acid (Empirin with codeine); codeine, acetylsalicylic acid, caffeine, and butalbital (Fiorinal); codeine, acetaminophen, caffeine, and butalbital (Fioricet); hydrocodone and acetaminophen (Anexsia, Anodynos-DHC, Co-Gesic, Dolacet, DuoCet, Hydrocet, Hydrogesic, Hy-Phen, Lorcet 10/650, Lorcet-HD, Lorcet Plus, Lortab, Margesic H, Medipain 5, Norco, Stagesic, T-Gesic, Vicodin, Vicodin ES, Vicodin HP, Zydone); hydrocodone and acetylsalicylic acid(Lortab ASA); hydrocodone and ibuprofen (Reprexain, Vicoprofen); opium and belladonna (B&O Supprettes); oxycodone and acetaminophen (Endocet, Percocet 2.5/325, Percocet 5/325, Percocet

7.5/500, Percocet 10/650, Roxicet 5/500, Roxilox, Tylox); oxycodone and acetylsalicylic acid (Endodan, Percodan, Percodan-Demi); pentazocine and acetaminophen (Talacen); pentazocine and acetylsalicylic acid (Talwin Compound); propoxyphene and acetaminophen (Darvocet-N, Darvocet-N 100, Pronap-100, Propacet 100, Propoxacet-N, Wygesic); propoxyphene and acetylsalicylic acid (Bexophene, Darvon Compound-65 Pulvules, PC-Cap); propoxyphene, acetylsalicylic acid, and caffeine (Darvon Compound).

Interaction Type and Significance

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

D-Phenylalanine (DPA) can limit the activity of enkephalinase, thereby inhibiting the breakdown of and increasing circulating levels of enkephalins, the endogenous neuropeptides with opiate-like activity in the brain.[4,27] Concomitant administration of opiate agent(s) and DPA could potentially produce an additive or synergistic effect as a result of DPA's effects on endogenous neurotransmitters and exogenous opiates. An adverse interaction is improbable because endorphins (i.e., enkephalins) do not suppress respiration; they would only potentiate the analgesic activity of opiates. Although premised on reasonable pharmacological principles, such interpretations are of necessity speculative, given the paucity of documented clinical data.

Research

Dove et al.[28] have conducted a series of animal experiments investigating the analgesic activity of DPA. In a mouse model, they determined that DPA produces dose-dependent analgesic effects, similar to well-established nonnarcotic analgesics, but with action significantly longer in duration. In rats they observed neither a tolerance to DPA after administration for 10 days, nor a development of drug dependence after treatment for 6 weeks. These researchers also reported that the analgesic action of DPA "has been demonstrated in hot-plate tests on mice that combining D-Phe with narcotic analgesics already with doses inactive on separate application." They observed that dosage of morphine could be reduced by half when combined with DPA, without reducing analgesic activity in rats. After 6 weeks of treatment, this combination "markedly lowered" typical adverse drug effects such as "dependence, behavioural disorders and growth retardation."[29]

In a review article, Russell and McCarty[30] discussed the activity of DL-phenylalanine (DLPA) greatly potentiating opiate analgesia as an example of "nutrient/pharmaceutical up-regulation of the endogenous analgesia system." Most available research indicates that the dosage of phenylalanine (DPA or DLPA) necessary for analgesic effect gradually declines over time with continued use.[3]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The administration of D-phenylalanine in conjunction with narcotic medications can be considered a reasonable option for integrative approaches to analgesia, especially in the treatment of chronic pain. Closely monitored therapeutic trials may show a safe, effective intervention in the treatment of severe and recalcitrant pain, pending well-designed, larger clinical trials. Available evidence suggests that such concomitant therapy may enable reduced opiate dosage, reduced adverse effects, and lessened susceptibility to the development of drug tolerance.

Naloxone

Naloxone (Narcan).

Interaction Type and Significance

◇ **Adverse Drug Effect on Nutritional Therapeutics, Strategic Concern**

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

Probability: **1. Certain**

Evidence Base: ● **Consensus**

Effect and Mechanism of Action

Naloxone hydrochloride acts as an opioid antagonist. D-Phenylalanine can limit the activity of enkephalinase, thereby inhibiting the breakdown and increasing circulating levels of enkephalins.[4,27]

Research

The inhibition of D-phenylalanine's analgesic effect by naloxone has been well established within pharmacology and physiology.[27,30,31] Naloxone has been clearly shown to block placebo pain responses, which are mediated by endorphins/enkephalins. DLPA can exert a placebo effect as well as a physiological response.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians: prescribing naloxone are advised to query patients as to whether they may also be using D- or DL-phenylalanine for pain relief. During use of naloxone, such patients experience reduced therapeutic efficacy of the nutrient.

Phenothiazine and Butyrophenone Typical Antipsychotic (Neuroleptic) Medications

Phenothiazines: Acetophenazine (Tindal), chlorpromazine (Largactil, Thorazine), fluphenazine (Modecate, Permitil, Prolixin, Prolixin Decanoate, Prolixin Enanthate), mesoridazine (Serentil), methotrimeprazine (levomepromazine; Nozinan), pericyazine (Neuleptil), perphenazine (Trilafon); combination drug: perphenazine and amitriptyline (Etrafon, Triavil, Triptazine); prochlorperazine (Compazine, Stemetil), promazine (Sparine), promethazine (Phenergan, Promacot, Promethegan), propiomazine (Largon), thiethylperazine (Torecan), thioproperazine (Majeptil), thioridazine (Mellaril), trifluoperazine (Stelazine), triflupromazine (Vesprin).

Butyrophenone neuroleptics: Benperidol (Anquil, Benperidol-neuraxpharm, Frenactil, Glianimon), droperidol (Dridol, Inapsine), haloperidol (Haldol), melperon (Buronil), triperidol (Trifluperidol).

Interaction Type and Significance

✗✗✗ **Potentially Harmful or Serious Adverse Interaction—Avoid**

Probability:
2. Probable

Evidence Base:
◉ Emerging

Effect and Mechanism of Action

Concomitant use of phenylalanine, a dopamine precursor, could theoretically increase the risk of developing neuroleptic-induced tardive dyskinesia (TD) by elevating levels of dopamine, norepinephrine, and epinephrine.

Research

Gardos et al.[32] observed a statistically significant correlation between Abnormal Involuntary Movements Scale (AIMS) total scores and plasma phenylalanine levels subsequent to a loading dose of 100 mg/kg phenylalanine. These researchers concluded that abnormalities in phenylalanine metabolism may contribute to the development and severity of TD in some unipolar depressed patients treated with neuroleptic medications. In a double-blind, placebo-controlled clinical trial involving 18 male schizophrenic patients with TD, Mosnik et al.[33] found that challenge with 100 mg/kg phenylalanine significantly exacerbated involuntary movements compared with placebo. In a subsequent experiment involving 25 patients, Schultz et al.[34] studied the magnitude of induced abnormal movements to assess factors influencing exacerbation of TD before and after oral administration of a phenylalanine challenge drink. They observed that lower fasting levels of phenylalanine and the severity of abnormal movements at baseline predicted greater movements in response to phenylalanine influx. This suggests that measuring fasting amino acid levels might enable clinicians to predict differences in vulnerability to drug-induced effects.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing haloperidol and related typical antipsychotic medications should advise patients to avoid consumption of supplemental phenylalanine and other isolated nutrients that may act as neurotransmitter precursors. Assessment of fasting amino acid levels might provide insight into risk of susceptibility to such exacerbation.

Selegiline, Phenylethylamine, and Monoamine Oxidase (MAO-B) Inhibitors

MAO-B inhibitors: Selegiline (deprenyl, L-deprenil, L-deprenyl; Atapryl, Carbex, Eldepryl, Jumex, Movergan, Selpak); pargyline (Eutonyl), rasagiline (Azilect).

Phenylethylamine (PEA)

See MAO-A inhibitors in Theoretical, Speculative, and Preliminary Interactions Research.

Interaction Type and Significance

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
◉ Emerging or
● Consensus

Effect and Mechanism of Action

Phenylalanine, particularly the D isomer (DPA), can be converted to phenylethylamine (PEA), an endogenous neuroamine that appears to elevate mood. Such coadministration might also produce a synergistic effect on neurotransmitter status in the treatment of individuals with depression and possibly Parkinson's disease.

Phenylalanine, particularly the L isomer, is also the precursor of tyrosine, and elevations in phenylalanine levels can increase levels of tyrosine. Increased tyrosine levels could raise monoamine neurotransmitters if monoamine oxidase (MAO), the enzyme that breaks down dopamine, norepinephrine, and other monoamines, is inhibited. As a result, the concomitant intake of MAO inhibitors and exogenous D- and/or L-phenylalanine could theoretically produce adverse effects associated with excessive tyrosine-derived neurotransmitters or DPA-derived PEA. This could result in a hypertensive crisis and the attendant risk of a heart attack or stroke.

Research

The coadministration of selegiline with D-phenylalanine, or PEA, may alleviate depression and improve mood. Such effects are sustained and have been noted in some patients who are unresponsive to conventional antidepressant treatment.[35] Phenylethylamine is an endogenous neuroamine that has been linked to the regulation of physical energy and attention, and high doses are known to produce significant mood-elevating effects, often compared to those of cocaine or methamphetamine. Investigators have found that PEA increases attention and activity in animals and has been shown to relieve depression in 60% of depressed patients, as demonstrated by urinary excretion of phenylacetic acid.[36] Several researchers have proposed that PEA deficit may be the cause of a common form of depressive illness.[37]

Phenylethylamine can be synthesized from both D-phenylalanine and L-phenylalanine. With L-phenylalanine being preferentially converted to L-tyrosine, the direct conversion to PEA makes D-phenylalanine the preferred substrate for increasing the synthesis of PEA. Normally, MAO-B selectively metabolizes phenylethylamine to phenylacetic acid. 2-Phenylethylamine is a metabolite of the MAO inhibitor antidepressant phenelzine, and concentrations of PEA are greatly increased in brain after administration of MAO inhibitor antidepressants. Further, PEA may be a neuromodulator of catecholamine activity.[38]

In a clinical trial involving 155 patients diagnosed with unipolar depression, Birkmayer et al.[39] demonstrated that enhanced antidepressive efficacy and beneficial effects in 90% of outpatients and 80.5% of inpatients treated with 5 to 10 mg L-deprenyl (selegiline) and 250 mg L-phenylalanine, administered daily, both orally and intravenously. These researchers conclude that "this combined treatment has a potent antidepressive action based on the accumulation of L-phenylethylamine in the brain."

In 1986, Sabelli et al.[36] published clinical studies on the phenylethylamine hypothesis of affective disorder in which they reported that decreased urinary levels of PEA (suggesting a deficiency) have been found in a significant portion of patients with depression. In two subsequent trials, Sabelli et al.[40,41] reported that the combination of selegiline and phenylalanine provided for "rapid treatment of depression," and that phenylethylamine relieves depression after selective MAO-B inhibition. In a small trial, published in 1991, ten patients with severe, intractable depression were treated with a daily cocktail of low-dose selegiline/L-deprenyl (5 mg), vitamin B_6 (100 mg), and L-phenylalanine (2-6 g). "Nine of 10 patients experienced mood elevation within hours of phenylalanine administration and 6 viewed their episodes of depression as terminated within 2 to 3 days."[40] Several years

later, this research team coadministered PEA (10-60 mg/day orally) and selegiline (10 mg/day to prevent rapid PEA destruction) to 14 patients with major depressive episodes. They found that 12 patients maintained an initial antidepressant response after 20 to 50 weeks, and that the necessary therapeutic dosage of PEA was stable over time, did not produce tolerance, and was not associated with any significant pattern of adverse effects.[37]

In a related study involving 20 healthy, regularly exercising young men, Szabo et al.[42] found that 24-hour mean urinary concentration of phenylacetic acid increased by 77% after a 30-minute bout of moderate to high intensity aerobic exercise. These findings were interpreted to demonstrate, or at least suggest, that PEA, as reflected in phenylacetic acid levels, may be a key factor in the therapeutic effects of physical exercise on depression.

In an experiment using squirrel monkeys, Bergman et al.[43] observed that inhibition of MAO-B, with *R*-(−)-deprenyl or MDL 72974, enhances discriminative-stimulus and reinforcing-stimulus effects of beta-PEA (0.3-1.0 mg/kg), presumably by delaying its inactivation. These researchers concluded that "MAO-B inhibition leading to increased levels of beta-PEA may be useful, alone or in combination with other therapeutic agents, in the pharmacological management of selected aspects of drug dependence."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Selegiline is an irreversible and (relatively) selective MAO-B inhibitor used in the treatment of Parkinson's disease and reported to induce an excess of mortality. The preliminary research available indicates that coadministration of selegiline and phenylalanine (in the D form or as the combined DL mixture) may, under proper medical supervision, reduce the necessary therapeutic dosage of the MAO inhibitor, thereby decreasing risk of drug-induced adverse effects.

Further research with well-designed clinical trials is warranted in the complex area of efficacy and safety of combining phenylalanine (in either form or as the combined DL mixture) with either type of MAO inhibitor.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Monoamine Oxidase (MAO-A) Inhibitors

Isocarboxazid (Marplan), moclobemide (Aurorix, Manerix), phenelzine (Nardil), procarbazine (Matulane), tranylcypromine (Parnate).

Phenylalanine, particularly the L isomer, is the precursor of L-tyrosine, and elevations in phenylalanine levels can lead to increased levels of tyrosine. Levels of tyrosine-derived neurotransmitters could rise to excessive levels if MAO, the enzyme that breaks down dopamine and other monoamines, is inhibited. Thus, the concomitant intake of MAO inhibitors and exogenous D-phenylalanine could theoretically produce adverse effects associated with excessive tyrosine-derived neurotransmitters, most notably a hypertensive crisis and the attendant risk of heart attack or stroke.

Prudence warrants the avoidance of concomitant administration of phenylalanine and MAO-A inhibitors. Nevertheless, evidence from qualified reports or human trials is lacking to characterize the theoretical interaction between MAO-A inhibitors and phenylalanine or establish the frequency or conditions of its occurrence. The suggested mechanism of action indicates that the outcome of such an interaction would primarily be determined by dosage, patient pharmacogenomics, and clinical management. Further research with well-designed clinical trials is warranted in the complex area of efficacy and safety of combining phenylalanine (in either form or as the combined DL mixture) with either type of MAO inhibitor.

NUTRIENT-NUTRIENT INTERACTIONS

Branched-Chain Amino Acids: Isoleucine, Leucine, Valine

Branched-chain amino acids (BCAAs: isoleucine, leucine, and valine) compete with phenylalanine and other aromatic amino acids for absorption and transport across the blood-brain barrier into the brain. Separating intake of phenylalanine (by at least 2 hours) from amino acids and meals high in protein will reduce interference with bioavailability and therapeutic action.

Vitamin B_6 (Pyridoxine)

Vitamin B_6 plays a key role in processing all amino acids. L-Phenylalanine activity is enhanced by simultaneous administration of vitamin B_6 (20-50 mg twice daily), especially in the treatment of depression.[40,44]

Preliminary research involving children with PKU indicates the possibility of reduced turnover of vitamin B_6 in PKU.[45]

Tyrosine

Phenylalanine is a precursor of tyrosine, and elevations in either (and especially both) can lead to excessive elevations in dopamine and norepinephrine. Because of the possible additive effect, avoid unmonitored concomitant administration of phenylalanine and tyrosine in depression. Potential additive effect with phenylalanine could theoretically increase the possibility of adverse effects within the context of MAO inhibitor therapy, as previously discussed.

When observed, high phenylalanine levels may be the result of high protein intake or a block in the conversion of phenylalanine to tyrosine (as occurs in PKU). Iron, vitamin C, and niacin are necessary for this enzymatic step. Check tyrosine level and, if low, administer tyrosine and iron.

The 45 citations for this monograph, as well as additional reference literature, are located under Phenylalanine on the CD at the back of the book.

Tryptophan

Nutrient Name: Tryptophan.
Synonyms: 1-Alpha-amino-3-indolepropionic acid, indole-alpha-aminopropionic acid, L-tryptophan, tryptophane, Trp.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Allopurinol ⊕⊕	Allopurinol inhibits hepatic tryptophan pyrrolase activity, thereby (apparently) decreasing tryptophan breakdown and increasing levels of serotonin and melatonin. Coadministration of L-tryptophan and allopurinol may be effective in treating depression, especially refractory cases. Clinical significance probable, but evidence lacking consistency and rigor.	Caution. Concomitant use could be therapeutic with appropriate clinical management.
Clorazepate ✗	Potential competition between clorazepate and tryptophan may interfere with drug activity. Mechanism plausible but evidence minimal.	Monitor if concomitant use required. Separate intake.
Fluoxetine Selective serotonin reuptake inhibitor and selective norepinephrine reuptake inhibitor (SSRI and SNRI) antidepressants ✗✗/⊕✗/⊕⊕	Combination of tryptophan's effect as serotonin precursor and activity of SSRI in inhibiting serotonin reuptake creates inherent risk of excessively elevated serotonin levels. This additive effect can result in rapid onset of severe symptoms but might also be applied purposefully within a tightly managed therapeutic protocol.	Generally avoid concomitant use. Transitional or continued concomitant use possible with close supervision and regular monitoring.
Lithium ⊕⊕/☼	Lithium increases serotonin release and decreases metabolism. Genetic variation in tryptophan hydroxylase may play role in variable efficacy of lithium. Tryptophan administration may enhance the therapeutic efficacy of lithium and allow for reduced adverse drug effects by enabling lower lithium dosage. Evidence mixed.	Concomitant use could be therapeutic with appropriate clinical management.
Phenelzine Monoamine oxidase (MAO-A) inhibitors ✗✗✗	Serotonin is metabolized by MAO to 5-hydroxyindoleacetic acid, so combination of MAO inhibition and increased tryptophan intake carries high probability of resulting in clinically significant serotonin excess and major risk of serious adverse effects.	Avoid concurrent use.
Sibutramine Serotonin agonists ✗✗✗	Serotonin agonists can increase serotonergic effect of tryptophan as a serotonin precursor, resulting in clinically significant serotonin excess and major risk of serious adverse effects.	Avoid concurrent use of tryptophan, as well as other serotonin agonists or precursors.
Tricyclic antidepressants (TCAs) ✗✗/⊕✗/⊕⊕	Tryptophan can potentiate action of TCAs through its serotonergic effects, which could result in excessively elevated serotonin levels. This additive effect can result in rapid onset of severe symptoms but might also be applied purposefully within a tightly managed therapeutic protocol.	Caution. Concomitant use could be therapeutic with appropriate clinical management.

NUTRIENT DESCRIPTION

Chemistry and Form

Levotryptophan, L-tryptophan.

Physiology and Function

Tryptophan is one of eight essential amino acids that must be obtained from the diet. Its primary functions include its role in niacin synthesis and as a precursor to both serotonin and melatonin. Approximately 98% of dietary L-tryptophan is metabolized into nicotinic acid (niacin), and only a very small amount is metabolized into serotonin via the intermediary stage of 5-hydroxytryptophan (5-HTP). The unusual indole side chain of tryptophan serves as the nucleus of serotonin. Serotonin is synthesized through a two-step process involving a tetrahydrobiopterin-dependent hydroxylation reaction (catalyzed by tryptophan-5-monooxygenase) and then a decarboxylation catalyzed by aromatic L-amino acid decarboxylase. Tryptophan hydroxylase (TPH) is the rate-limiting biosynthetic enzyme in the serotonin pathway, regulates levels of serotonin, and is normally only about half-saturated. Serotonin is present at highest concentrations in platelets and in the gastrointestinal (GI) tract. Lesser amounts are found in the brain and the retina. Serotonin in the central nervous system (CNS) is metabolized by monoamine oxidase to 5-hydroxyindoleacetic acid (5-HIAA).

Melatonin (*N*-acetyl-5-methoxytryptamine) is derived from serotonin within the pineal gland and the retina, where the necessary *N*-acetyltransferase enzyme is found.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Anodyne, antidepressant, antihyperglycemic, antihypertensive, galactagogue, melatonin precursor, niacin precursor, sedative, serotonin precursor.

Possible Uses

Agalactia, anorexia, bulimia, appetite suppression, bipolar disorder, carcinoid syndrome, dementia, depression, fibromyalgia, Hartnup's disease, hypertension, insomnia, mania,

menopausal symptoms, migraine headaches, obesity, pain syndromes, parkinsonism, phenylketonuria, psychosis, premenstrual syndrome, schizophrenia, serotonin deficiency syndrome.

Deficiency Symptoms

A deficiency of tryptophan may lead to depression, edema, hair depigmentation, insomnia, lethargy, liver damage, muscle loss, pellagra, slowed growth in children, and suicidal thoughts. Metabolic disturbances associated with tryptophan deficiencies are carcinoid syndrome and Hartnup's disease. Symptoms of serotonin deficiency syndrome (SDS) include nervousness, anxiety, sleep disorders, mood disorders, and excessive appetite.

Dietary Sources

Tryptophan is the least abundant amino acid in foods. It tends to be deficient in most dietary proteins and has an uneven distribution. The richest dietary sources include fish, meat, dairy, eggs, nuts, and wheat germ. The seeds of evening primrose are a particularly rich plant source of tryptophan. There is lingering controversy as to the degree to which dietary levels of tryptophan intake affect serotonin and melatonin levels.

Dosage Forms Available

Capsule.

Source Materials for Nutrient Preparations

Synthetic L-tryptophan is manufactured by a fermentation process using pure glucose as a substrate. The products of fermentation are then separated and purified by filtration and purification procedures.

Dosage Range

Adult

Dietary: Minimum daily requirements are estimated as 0.25 g for males and 0.15 g for females.

Average U.S. daily intake: 1.0 to 1.5 g.
Recommended dietary allowance (RDA): 200 mg per day.

Supplemental/Maintenance: Supplementation usually not necessary.
Pharmacologic/Therapeutic: 0.5 to 4.0 g per day, short-term use. Occasionally, doses of 8 to 12 g daily, given in three or four equally divided doses, are used in the treatment of depression.

When L-tryptophan is prescribed within the context of integrative clinical management, the dosage will typically start low and increase gradually as needed. Clinical response will often require 60 days to demonstrate full benefits. Daily dosage usually does not exceed 1 gram per 100 pounds of body weight (1 g/100 lb).
Toxic: 7 g per 150 lb body weight.

SAFETY PROFILE

Overview

L-Tryptophan is an essential amino acid generally considered to have a low risk of toxicity, when used at typical dietary or supplemental intake levels, barring contraindications.

Nutrient Adverse Effects

General Adverse Effects

Anorexia, dizziness, drowsiness, dry mouth, headache, nausea, sexual disinhibition.

Long-term supplementation or treatment with tryptophan may increase plasma levels of other amino acids, potentially resulting in various adverse effects.

Adults

Studies in humans have shown that 100 mg/kg/day of tryptophan, corresponding to 7 g/150 lb, can cause gastric irritation, vomiting, and head twitching. A dosage of 800 mg/kg given to rhesus monkeys did not produce detectable clinical adverse effects.

Although tryptophan is a naturally occurring substance in the body, controversies surround serious adverse reactions to reported contaminants in both L-tryptophan and 5-HTP.

Special Issues

During 1989, 35 deaths and many cases of severe allergic reaction, in the form of the eosinophilia-myalgia syndrome characterized by high eosinophil counts, scleroderma-like muscle pain, and thickening of the skin, were associated with consumption of tryptophan supplements. The Food and Drug Administration (FDA) removed L-tryptophan from the U.S. market by pursuant to these events. Subsequent investigation determined that a single manufacturer in Japan had employed a new bacterial strain to synthesize L-tryptophan, and that this bacterium had introduced toxic byproducts that contaminated particular batches of the product.

As a serotonin precursor, L-tryptophan intake could theoretically contribute to "serotonin syndrome," an excess accumulation of serotonin in the synapses, characterized by altered mental states, autonomic dysfunction, and neuromuscular abnormalities (see later discussion).

Mutagenicity

Animal tests involving oral or subcutaneous administration of L-tryptophan or its metabolites have not yielded evidence of statistically significant increases in incidence of neoplasms. However, evidence indicates that foods containing tryptophan may carry an increased risk of carcinogenicity, especially to breast and bladder tissues, when they have been charbroiled or heated to high temperatures.

Life Stage

Inadequate research-based evidence exists to demonstrate any particular age-related effects on pediatric or geriatric populations as a result of increased tryptophan intake.

Pregnancy and Nursing

Well-designed controlled clinical trials with human subjects have not been undertaken, nor have case reports been qualified and systematically analyzed, regarding effects of L-tryptophan during pregnancy or breastfeeding. In some animals the equivalent of 8 g per day was found to be teratogenic. However, L-tryptophan intake by pregnant women and lactating mothers has not been shown to cause birth defects or other pregnancy or lactation problems. It is not known whether L-tryptophan passes into breast milk. However, L-tryptophan has not been reported to cause problems in nursing babies. Nevertheless, caution should be used with supplementation or administration during pregnancy or breastfeeding, and any such usage during pregnancy should be supervised and closely monitored.

Laboratory Values

Tryptophan levels in the blood vary greatly when measured by different laboratories. Tryptophan can be measured by fluorometric and high-performance liquid chromatography (HPLC) techniques. Some experts believe chromatography may be the most accurate. Other, indirect methods can also be employed, such as the tryptophan load test. This test involves measuring a metabolite of tryptophan, xanthurenic acid, in the urine after a standard 2-g dose is given. The more xanthurenic acid found in the urine, the greater is the need for either vitamin B_6 or tryptophan.

Contraindications

Achlorhydria, bladder cancer, cataracts, diabetes mellitus, female infertility, pregnancy, psoriasis; sensitivity to L-tryptophan. May exacerbate rheumatoid arthritis.

Precautions and Warnings

L-Tryptophan is best taken with a low-protein, carbohydrate-rich meal or snack to minimize risk of digestive distress. Also, an insulin response to carbohydrate facilitates transfer of serum tryptophan into the CNS (thought to be the reason serotonin-deficient people crave carbohydrates). Minimizing concomitant protein intake decreases competition between tryptophan and other dietary protein–derived amino acids for transport through the blood-brain barrier.

INTERACTIONS REVIEW

Strategic Considerations

The therapeutic effects of L-tryptophan, especially as an antidepressant, are related to its ability to increase serotonin synthesis in the CNS. Emerging research indicates that baseline availability of L-tryptophan, prolactin, and large, neutral amino acids (LNAAs) are key factors that predict response to antidepressant treatment in major depression. The major concern with tryptophan supplementation or administration with regard to drug interactions is the risk of inducing serotonin syndrome. This potentially dangerous situation results from an excess serotonin availability in the CNS at the 5-HT1A receptor; some interaction with dopamine and 5-HT2 receptors is also likely to be involved. Clinical trials have demonstrated that L-tryptophan causes a significant increase in the level of the serotonin metabolite, 5-HIAA, in the lumbar cerebrospinal fluid, corresponding to an increased turnover of serotonin in the CNS.

Serotonin syndrome carries potentially serious clinical consequences and is characterized by the triad of altered mental status, autonomic dysfunction, and neuromuscular abnormalities. The serotonin syndrome is similar to the neuroleptic malignant syndrome and is usually differentiated by the setting of recent addition of a serotonergic agent. Specific symptoms can include agitation, anxiety, ataxia, confusion, delirium, diaphoresis, diarrhea, fever, hyperreflexia, myoclonus, incoordination, shivering, nausea, vomiting, or tremor. This phenomenon most often occurs in the presence of selective serotonin reuptake inhibitors (SSRIs), monoamine oxidase (MAO) inhibitors, opioids, and other serotonergic agents, when the serotonin system has been modulated by another serotonergic agent or compromised by illness. SSRIs, particularly fluoxetine, are most frequently involved in reported instances of drug interactions inducing serotonin syndrome; as a consequence of their long elimination half-life (1 week for fluoxetine), the risk of interactions persists for several days or even weeks after SSRI withdrawal.

Many clinicians and some researchers have investigated potential synergistic benefits from coadministration of tryptophan and various psychoactive pharmaceutical agents. Although the consequences of adverse effects can be clinically significant, the available evidence suggests that such risk is less probable, and adverse effects less severe, with tryptophan than with 5-HTP. Caution is requisite to use of tryptophan, in any dose, during antidepressant or other medication therapy, and this warrants close supervision and regular monitoring within an integrative context. 5-HTP should never be combined with SSRIs or MAO inhibitors in any dose, except possibly in a carefully monitored inpatient clinical research setting.

NUTRIENT-DRUG INTERACTIONS

Allopurinol

Allopurinol (Oxypurinol; Aloprim, Apo-Allopurinol, Lopurin, Purinol, Zyloprim).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action

Human and animal studies consistently indicate that allopurinol causes elevated brain levels of tryptophan.[1,2] Allopurinol is a xanthine oxidase inhibitor and is typically used to lower blood levels of uric acid to prevent gout and adjunctively with certain forms of chemotherapy. However, allopurinol also inhibits hepatic tryptophan pyrrolase activity and prevents the reduction in the indole levels induced by heme precursor 5-aminolevulinate (5-ALA). Daytime administration of 5-ALA can reduce brain tryptophan and serotonin levels because of saturation of liver tryptophan pyrrolase. Saturation of this enzyme with heme results in enhanced activity, leading to increased catabolism of tryptophan and thus making less tryptophan available to the brain. Thus, Daya et al.[3] demonstrated that 5-ALA alters brain tryptophan and serotonin levels without changing pineal serotonin and melatonin concentrations. It is hypothesized that increased levels of serotonin and melatonin, as a result of decreased tryptophan breakdown, can result in an antidepressant and analgesic effect.

Research

Over the decades, research on the effects of inhibition of tryptophan pyrrolase by allopurinol has elicited several distinct patterns but evolved to no certain conclusion. Many (but not all) studies have observed measurable effects of allopurinol on tryptophan metabolism.[4,5] Green et al.[6] investigated the effect of oral administration of allopurinol (300 mg daily) or nicotinamide (500 mg twice daily) on the metabolism of an oral L-tryptophan load (50 mg/kg). Their findings were interpreted to suggest that allopurinol and nicotinamide were unlikely to be of value as tryptophan pyrrolase inhibitors in vivo and therefore would not increase the therapeutic effect of L-tryptophan when given to treat depressive illness. However, Stern and Mendels[7] reviewed a preliminary study involving eight individuals diagnosed with refractory depression using a

combination of L-tryptophan and allopurinol. The investigators reported that five of the trial participants demonstrated full remission. Throughout the course of study on this topic, the various authors have continued to stress the need for further, double-blind, controlled studies to evaluate the safety and efficacy of this combination therapy.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Controlled clinical trials will be necessary to determine whether the adjunctive use of allopurinol during tryptophan therapy can provide clinical efficacy in the treatment of depression or other conditions responsive to tryptophan supplementation. In the meantime, health care practitioners experienced in therapeutic nutrition and qualified in conventional pharmacology who might be interested in experimenting with this potential synergistic therapy at low dosage levels, and possible gradual escalation, are advised to supervise and regularly monitor any such patients. No investigators have expressed concern with adverse effects from this interaction, but such clinical practice is recommended as judicious.

Clorazepate

Clorazepate (Gen-Xene, Tranxene).

Interaction Type and Significance

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

Probability: **4. Plausible**

Evidence Base: ☐ **Inadequate**

Effect and Mechanism of Action

L-Tryptophan and dipotassium clorazepate potentially compete, such that high intake of tryptophan might interfere with the intended therapeutic action of the medication.

Research

In vitro research by Coassolo et al.[8] demonstrated the competitive binding of L-tryptophan and dipotassium clorazepate, a benzodiazepine, for human serum albumin.

Clinical Implications and Adaptations

Further research, preferably human clinical trials, is needed to determine the probability, risk settings, and clinical significance of this plausibly significant interaction. Separate intake if concomitant use necessary.

Fluoxetine and Related Selective Serotonin Reuptake Inhibitor and Serotonin-Norepinephrine Reuptake Inhibitor (SSRI and SNRI) Antidepressants

Evidence: Fluoxetine (Prozac, Sarafem).
Extrapolated, based on similar properties: Citalopram (Celexa), duloxetine (Cymbalta), escitalopram (S-citalopram; Lexapro), fluvoxamine (Faurin, Luvox), paroxetine (Aropax, Deroxat, Paxil, Seroxat), sertraline (Zoloft), venlafaxine (Effexor).

Interaction Type and Significance

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **1. Certain**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

L-Tryptophan acts as a serotonin precursor, and the selective serotonin reuptake inhibitors (SSRIs) are designed to increase the functional level of serotonin in the brain by inhibiting its reuptake into the presynaptic neurons. Fluoxetine is a potent and selective inhibitor of presynaptic serotonin reuptake, therefore increasing the amount of serotonin in the synaptic cleft. Increased intake of L-tryptophan can potentially elevate levels of serotonin in the CNS. Such concomitant elevation of serotonin and inhibition of its reuptake presents both the opportunity for possible therapeutic synergy and the risk of potentially dangerous serotonin excess.

Research

In an early trial involving zimelidine for the treatment of depression, Walinder et al.[9] found that the administration of the relatively high dose of 45 mg per pound body weight of DL-tryptophan, a synthetic variation of L-tryptophan, did not result in adverse effects. Zimelidine is an SSRI medication, similar in action to paroxetine, that was withdrawn worldwide in September 1983 because of the risk of Guillain-Barré syndrome associated with its use.

Research into the relationship between tryptophan depletion and the therapeutic mechanisms and efficacy of SSRI medications provides useful data in understanding the tryptophan-SSRI interaction pattern. Short-term reduction in plasma tryptophan (tryptophan depletion) produces a relapse of depressive symptoms in 60% of previously depressed patients recently recovered with SSRI treatment. Barr et al.[10] investigated the hypothesis that SSRI treatment itself may confer vulnerability to the development of depressive symptoms during tryptophan depletion. They conducted a double-blind placebo-controlled involving six healthy individuals who underwent tryptophan depletion before and after 6 weeks of treatment with fluoxetine, 20 mg/day. Their findings showed no increased vulnerability to the mood-lowering effects of tryptophan depletion as a result of fluoxetine treatment. From these data the researchers determined that treatment with SSRIs alone does not produce the depressive effects of tryptophan depletion observed in SSRI-treated depressed and obsessive-compulsive disorder patients.

In a subsequent trial looking at the differential pathways of antidepressant action in desipramine and fluoxetine, Delgado et al.[11] studied 55 individuals diagnosed with, but not currently medicated for, depression who were randomly assigned to antidepressant treatment with either desipramine or fluoxetine, then administered amino acid drinks capable of inducing tryptophan depletion. Whereas eight (of 15) fluoxetine responders reported relapse of significant depressive symptoms, only one (of 15) of the desipramine responders and none of the control subjects relapsed. The researchers concluded that rapid depletion of plasma tryptophan transiently reverses the antidepressant response in many patients taking fluoxetine, but not desipramine, and that antidepressant response to fluoxetine appears to be significantly dependent on serotonin (5-HT) availability. An important finding of this study is that various SSRI antidepressants mediate their therapeutic effects through different mechanisms. Recent investigation by Porter et al.[12] into the connection between tryptophan availability and variable response to different antidepressant medications further demonstrates that patients with a tryptophan level below the

mean improved significantly more than those with a higher level but with comparable serum steady-state drug levels.

Meltzer et al.[13] have found that fluoxetine potentiates the 5-HTP-mediated increase in plasma cortisol and prolactin secretion in subjects with major depression or with obsessive-compulsive disorder.

More directly, Levitan et al.[14] conducted a randomized, double-blind, placebo-controlled trial that examined the antidepressant and hypnotic effects of combining tryptophan and fluoxetine. In this small, preliminary clinical study, 30 individuals diagnosed with major depressive disorder were treated with fluoxetine and either tryptophan or placebo for 8 weeks. The investigators concluded that "combining 20 mg of fluoxetine with 2 g of tryptophan daily at the outset of treatment for major depressive disorder appears to be a safe protocol that may have both a rapid antidepressant effect and a protective effect on slow-wave sleep." The cumulative message of the assembled research strongly suggests that large-scale, well-designed clinical trials are warranted to confirm and clarify the emerging pattern indicated by the various findings.

No available report or trial evidence suggests an adverse interaction response when fluoxetine has been combined with a protein-rich diet containing significant levels of L-tryptophan.

Reports

Unsupervised coadministration of an SSRI agent with tryptophan carries a moderate risk for higher incidence of serotonin-associated unintended effects and adverse events. Specifically, reports have suggested that when taken in the form of a nutraceutical, L-tryptophan can interact adversely with fluoxetine, resulting in the following adverse effects, which are not associated with either drug alone: agitation, restlessness, poor concentration, nausea, diarrhea, and worsening of obsessive-compulsive disorder. These apparently interaction-induced symptoms disappeared as soon as the tryptophan was discontinued.[15-17] In a review of five case reports, Steiner and Fontaine[18] noted that signs and symptoms of CNS toxicity, both central and peripheral, developed within a few days of adding tryptophan (1-4 g/day) to ongoing fluoxetine therapy. Typical symptoms included nausea and vomiting, agitation, anxiety and restlessness, headache, dizziness, and increased perspiration.

Clinical Implications and Adaptations

A review of the evidence suggests an emerging, but not yet coherent and articulate, consensus supporting the proposition that L-tryptophan, in graduated dosages in the range of 2 to 4 g daily, can be used adjunctively with SSRI medications to enhance the clinical effectiveness of treatment for depression and other appropriate conditions. The ability of tryptophan to enhance, but not necessarily forcefully elevate, serotonin levels appears to exert a beneficial synergistic effect in conjunction with fluoxetine and some other SSRIs. However, the variable mechanisms of action among different SSRIs, along with individual pharmacogenomic variability, life stage and gender factors, and other metabolic influences, may account for differing therapeutic responses and occurrences of adverse effects.

Such an integrative therapeutic strategy warrants close supervision and regular monitoring within the context of coordinated care by health providers trained and experienced in both clinical nutrition and conventional pharmacology. However, the concomitant use of supplemental L-tryptophan and an SSRI such as fluoxetine outside such a context of active clinical management is contraindicated and potentially dangerous. A rapid onset of symptoms indicating an adverse response, particularly CNS toxicity, is highly probable in the event that a serotonin syndrome reaction or other adverse event does develop.

All available evidence strongly indicates that tryptophan-related data cannot be extrapolated to a clinical opportunity for safely combining 5-HTP and SSRI medications, and that all warnings and contraindications are amplified.

Lithium Carbonate

Lithium carbonate (Camcolit, Carbolith, Duralith, Eskalith, Li-Liquid, Liskonum, Litarex, Lithane, Lithobid, Lithonate, Lithotabs, PMS-Lithium, Priadel).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Lithium intake raises cortisol levels, and both lithium and supplemental tryptophan can elevate serotonin and cortisol levels as part of their therapeutic action. Concomitant use of these agents may induce excessively elevated serotonin levels and disrupt regulation of cortisol and other neuroendocrine substances.

Research

Lithium increases serotonin release and decreases metabolism. Despite lithium's proven efficacy as a long-term treatment for recurrent mood disorders (bipolar syndromes), individuals show a variable response, ranging from complete efficacy to no influence at all.[19,20] Serotonergic pathways appear to be of importance in the mechanisms of the action of lithium. Much recent research has focused on identifying possible predictors of response through molecular genetic studies. Recent research has observed an association between genetic variation in tryptophan hydroxylase (TPH) and aggressive and anger-related traits.[21] It is becoming apparent that clinical predictors account for about half the variance in lithium response, and genetic factors probably play a substantial role in both risk factors and response factors in affective disorders.[22-25]

In 1999, Serretti et al.[26] published one of several papers examining the possible association between the TPH gene variants and prophylactic efficacy of lithium in mood disorders. In a review from 2002, Serretti[27] reported that the functional polymorphism in the upstream regulatory region of the serotonin transporter gene (5-HTTLPR) has been associated with long-term efficacy of lithium in two independent studies; marginal associations have been reported for TPH and inositol polyphosphate 1-phosphatase (INPP1). Even though no unequivocal susceptibility gene for lithium efficacy has been identified, individual pharmacogenomic variability significantly influences response patterns. Within that context, manipulation of tryptophan metabolism and serotonin synthesis appears to play an important role.

In 1983, Brewerton and Reus[28] published the results of a small, double-blind clinical trial in which lithium therapy for bipolar disorder or schizoaffective disorders generated significantly enhanced outcomes with adjunctive administration of L-tryptophan, 2 to 4 g three times daily.

Reports

Clinical observations suggest that L-tryptophan can serve as a clinically effective adjunct to lithium therapy, particularly in the treatment of some individuals diagnosed as bipolar with mania or depression for whom lithium, alone or in combination with neuroleptics or tricyclics, has demonstrated limited or no effect.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

L-Tryptophan offers a valuable adjunct to lithium therapy in the management of some individuals with bipolar affective disorders. In addition to enhanced therapeutic efficacy, such coordinated administration of lithium and L-tryptophan provides an opportunity to reduce lithium doses and decrease attendant adverse effects, particularly in controlling acute mania and other severe conditions for which higher, more toxic doses of lithium are often required. Concomitant therapy may also achieve therapeutic efficacy with some individuals previously unresponsive to lithium alone or in combination with other psychoactive agents.

Some bipolar patients have demonstrated an increased sensitivity to L-tryptophan administration, with adverse reactions occurring at levels as low as 1 to 2 g daily. Low initial dose levels, slow and graduated increases in dosage, and regular monitoring are important to safe and effective concomitant medication.

L-Tryptophan, when administered to individuals undergoing lithium therapy, might increase some adverse effects associated with lithium therapy by potentiating the lithium effect; these include nausea, vomiting, dermatological eruptions, psoriasis, and alopecia. Gradual reduction of lithium in chronic cases, such as treatment of bipolar disorder, not only may be valuable for reduction of typical adverse effects associated with lithium, but also may be necessary because of an increase in lithium concentrations resulting from potentiation by L-tryptophan. Monitoring lithium concentrations for at least 2 weeks after introduction of L-tryptophan or making changes in lithium dosage is appropriate with such individuals. Individuals being treated for acute mania may be particularly sensitive to exacerbations because of alterations in effective concentrations of lithium. In such cases it may be appropriate to decrease the lithium dosage, especially with doses above 900 to 1200 mg per day. Implementation of such integrative strategies warrants active supervision and close monitoring by health care professionals trained and experienced in clinical nutrition and conventional pharmacology. Pharmacogenomic variability, particularly involving TPH polymorphisms, appears to influence both individual susceptibility to bipolar disorder and related conditions and therapeutic response to lithium and L-tryptophan.

Phenelzine and Related Monoamine Oxidase (MAO) Inhibitors

Evidence: Phenelzine (Nardil).
Extrapolated, based on similar properties: MAO-A inhibitors: Isocarboxazid (Marplan), moclobemide (Aurorix, Manerix), procarbazine (Matulane), tranylcypromine (Parnate).
Related but evidence lacking for extrapolation: MAO-B inhibitors: Pargyline (Eutonyl), rasagiline (Azilect), selegiline (deprenyl, L-deprenil, L-deprenyl; Atapryl, Carbex, Eldepryl, Jumex, Movergan, Selpak).

Interaction Type and Significance

✗✗✗ **Potentially Harmful or Serious Adverse Interaction—Avoid**

Probability: **1. Certain**

Evidence Base: ● **Consensus**

Effect and Mechanism of Action

The MAO-A inhibitor medications elevate serotonin concentrations because CNS serotonin is metabolized by monoamine oxidase (MAO) to 5-hydroxyindoleacetic acid (5-HIAA). Concomitant intake of L-tryptophan can then result in amplified serotonergic effects.

Research

Combined use of tryptophan and MAO inhibitors increases the risk of adverse drug effects. MAO inhibitors can induce potentiation of sympathomimetic substances and related compounds and result in a hypertensive crisis.

Reports

The most common adverse effects caused by the combination of L-tryptophan and MAO inhibitors are nausea, dizziness, and headache, usually immediately or shortly after coadministration. L-Tryptophan, 20 to 50 mg/kg, and MAO inhibitors, at standard therapeutic dosages, when taken together, have been reported to cause drowsiness, ethanol-like intoxication, hyperreflexia, and clonus. Levy et al.[29] documented three cases of multiple adverse effects from phenelzine-tryptophan combination treatment, including myoclonus, hyperreflexia, and diaphoresis.[29] Single case reports of adverse reactions to the drug combination include confusional states, hypomanic behavior, ocular oscillation, ataxia, and myoclonus.[30-33] On occasion, reactions have approached the severity of classic serotonin syndrome with tremor, hypertonus, myoclonus, and hyperreactivity. Reports concur that such symptoms resolve shortly after cessation of L-tryptophan intake; no detrimental long-term effects have been documented.

Clinical Implications and Adaptations

The concomitant use of tryptophan and MAO inhibitors represents a particularly high probability of clinically significant adverse effects and is strongly contraindicated. Individuals taking phenelzine or other MAO inhibitors should avoid unsupervised supplemental intake of L-tryptophan. Similar adverse reactions are known to occur with concomitant use of MAO inhibitors and sympathomimetic drugs (including amphetamines, cocaine, methylphenidate, dopamine, epinephrine, and norepinephrine) or related compounds (e.g., methyldopa, L-dopa, L-tyrosine, ephedra, ephedrine, pseudoephedrine, phenylalanine), as well as food sources of tyramine, such as red wine and aged cheese.

Sibutramine and Other Serotonin Agonists

Evidence: Sibutramine (Meridia, Reductil).
Extrapolated, based on similar properties: Almotriptan (Axert), buspirone (Buspar), dihydroergotamine (DHE-45), ergotamine, eletriptan (Relpax), frovatriptan (Frova), naratriptan (Amerge), rizatriptan (Maxalt), sumatriptan (Imitrex), zolmitriptan (Zomig).

Interaction Type and Significance:

✗✗✗ **Potentially Harmful or Serious Adverse Interaction—Avoid**

Probability: **1. Certain**

Evidence Base: ● **Consensus**

Effect and Mechanism of Action

Serotonin agonists can enhance the serotonergic effect of other serotonin agonists, as well as serotonin precursors, thereby increasing the risk of augmenting serotonin activity to toxic levels.[34] In particular, the additive effect on serotonin activity resulting from concomitant use of L-tryptophan and pharmaceutical serotonin agonists presents a significant risk of inducing serotonin syndrome.

Reports

The product information provided by the manufacturer of sibutramine states that "because [sibutramine] inhibits serotonin reuptake, it should not be administered with other serotonin agonists."[35]

Clinical Implications and Adaptations

The concomitant use of L-tryptophan and agents that enhance serotonin activity is contraindicated and should be undertaken only in the context of close clinical supervision and regular monitoring. Adverse effects of a dangerous additive interaction are likely to be characterized by rapid onset of toxicity symptoms.

Tricyclic Antidepressants (TCAs)

Evidence: Clomipramine (Anafranil), imipramine (Janimine, Tofranil).
Extrapolated, based on similar properties: Amitriptyline (Elavil); combination drug: amitriptyline and perphenazine (Etrafon, Triavil, Triptazine); amoxapine (Asendin), desipramine (Norpramin, Pertofrane), doxepin (Adapin, Sinequan), nortriptyline (Aventyl, Pamelor), protriptyline (Vivactil), trimipramine (Surmontil).
Related, no longer on market: Zimelidine.

Interaction Type and Significance

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: **▽ Mixed**

Effect and Mechanism of Action

L-Tryptophan can potentiate the action of tricyclic antidepressants (TCAs) through its serotonergic effects.

Research

A review of the research literature and clinical practice observations suggest clinically significant variability in the character and significance of interactions between L-tryptophan and various TCAs. Human clinical trials indicate that the dosage levels of L-tryptophan administration and the mechanism of action of the particular TCA affected the character and strength of potential interactions with TCAs. In a human trial, Chouinard et al.[36] enhanced imipramine therapy for bipolar disorder by expanding the therapeutic strategy to incorporate L-tryptophan (6 g/day) and niacinamide (1500 mg/day), compared with imipramine alone. Lower adjunctive doses of L-tryptophan (4 g/day) and niacinamide (1000 mg/day) suggested a significant but less efficacious effect in potentiating imipramine compared with the higher levels of administration. However, when the higher levels of L-tryptophan and niacinamide were administered to individuals diagnosed with depression, evidence of synergistic benefit was lacking.

Related research on antidepressant therapy using other TCAs demonstrated that larger dosages of L-tryptophan did not contribute to increased therapeutic benefit, with 6 g daily failing to provide therapeutic effect, whereas 4 g daily demonstrated therapeutic efficacy.[37] In a placebo-controlled trial with 24 individuals, Walinder et al.[38] found "significantly more rapid improvement" in those administered L-tryptophan with clomipramine than in those given clomipramine with placebo for endogenous depression, "especially with regard to the depression-anxiety cluster of symptoms." In contrast, further research by Walinder et al.[9] found that tryptophan in combination with zimelidine was not superior to zimelidine with placebo with respect to antidepressant activity. Recent investigation by Porter et al.[12] and others into the connection between tryptophan availability and variable response to different antidepressant medications shows that patients with tryptophan level below the mean improved significantly more than those with a higher level but with comparable serum steady-state drug levels.

Thus, human clinical trials indicate that the dosage levels of L-tryptophan and preexisting endogenous blood levels of the amino acid, as well as the mechanism of action of the particular TCA, affected the character and strength of potential synergistic interactions between tryptophan supplementation and TCAs.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The coordinated administration of TCAs and L-tryptophan can achieve clinically significant synergistic effect within the context of an integrative therapeutic strategy. Pretreatment tryptophan depletion status and carefully calibrated dosages of L-tryptophan, typically 4 g daily, appear to be primary factors in determining probability of optimal effect. Once stabilization occurs, reduction of antidepressant levels can be considered if consistent with the expressed patient treatment goals, particularly with a history of adverse effects attributable to the TCA. Evolving personalized treatment protocols with close supervision and regular monitoring by health care professionals trained and experienced both in nutritional therapeutics and conventional psychopharmacology offer opportunities for deriving clinical benefits greater than what might be achieved by conventional antidepressant medications alone.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Numerous discussions have arisen as to whether data and conclusions from potential or documented interactions involving 5-HTP can be reasonably extended to L-tryptophan, or vice versa. However, a critical difference between tryptophan and 5HTP is that the 5-hydroxy form only requires decarboxylation to become 5-hydroxytryptamine (5-HT, serotonin). Tryptophan has much greater metabolic physiological flexibility; it can be made into niacin or serotonin, or melatonin via serotonin, whereas 5-HTP is committed to the serotonin pathway. As previously noted, approximately 98% of dietary L-tryptophan is metabolized into nicotinic acid (niacin). Further, some research indicates that eating a diet high in tryptophan does not significantly increase 5-HTP levels. Thus, in contrast to 5-HTP, tryptophan may be able to enhance, but not necessarily forcefully elevate, serotonin levels in such a way as to allow for systemic equilibration

through negative-feedback loops within neurohormonal self-regulatory systems. Clinically, this means that 5-HTP has a much greater risk of resulting in a significant serotonin syndrome when combined with a pharmaceutical agent, particularly an SSRI or MAO inhibitor. In cases other than where evidence directly demonstrates such interactions involving tryptophan itself, such extrapolation (from interactions involving 5-HTP) warrants attention as "possible," but cannot be defined as an evidence-based interaction in the absence of direct data from human clinical trials, or at least case reports specifically involving L-tryptophan. Also, adverse reactions and interactions involving L-tryptophan are much less common than might have been the case before 1989, since L-tryptophan now requires a prescription, generally filled by a compounding pharmacy. 5-HTP is widely available in health food stores as a dietary supplement. This state of affairs is somewhat ironic because 5-HTP has a much narrower therapeutic dose range and is much more prone to cause adverse reactions (particularly nausea) than L-tryptophan. Time-release preparations of 5-HTP, which can be obtained from compounding pharmacists, largely avert problems with nausea.

Consult the 5-HTP monograph for interaction issues specifically involving that substance. Clinically, the behavior and interactions of tryptophan and 5-hydroxytryptophan are quite different. Experience with one should never be extrapolated to the other, despite their chemical similarity and metabolic relationship.

NUTRIENT-NUTRIENT INTERACTIONS

Large, Neutral Amino Acids: Tyrosine, Phenylalanine, Valine, Leucine, Isoleucine

Tryptophan competes with the other large, neutral amino acids (LNAAs)—tyrosine, phenylalanine, valine, leucine, and isoleucine—for transport across the blood-brain barrier. When tryptophan is therapeutically administered, it is usually given with vitamin B_6, apart from meals, with a small amount of carbohydrate to facilitate uptake by the brain. Tryptophan's action can also be supported by coadministration of vitamins B_3 and C, the other cofactors necessary for its metabolism.

The 38 citations for this monograph, as well as additional reference literature, are located under Tryptophan on the CD at the back of the book.

Tyrosine

Nutrient Name: Tyrosine.
Synonym: L-Tyrosine
Related Substance: L-Phenylalanine.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Amphetamines Dextroamphetamine Methylphenidate ⊕⊕/≈≈/☼	Tyrosine administration may enhance dopamine synthesis through its role as a precursor of L-dopa. Coadministration of L-tyrosine may reverse or prevent tyrosine depletion caused by amphetamines and support activity of amphetamine therapy by enhancing precursor availability. Adverse effects improbable. Research with well-designed trials warranted.	Coadministration may enhance therapeutic outcomes within integrative strategy, particularly with tyrosine depletion. Supervise, monitor, and titrate.
Imipramine Tricyclic antidepressants (TCAs) ⊕⊕	Tyrosine is a precursor to many neurotransmitters, including dopamine. Coadministration of tyrosine and L-tryptophan with imipramine may facilitate withdrawal in cocaine addiction. Evidence mixed and limited. Further research warranted.	Consider coadministration with close supervision. Monitor and titrate.
Levodopa Antiparkinsonian medications ◈◈/⊕✗/◈≈≈/☼/⊕⊕	Tyrosine administration may enhance dopamine synthesis through its role as a precursor of L-dopa. L-tyrosine may benefit Parkinson's patients. However, limited knowledge regarding potential issues of competition in absorption, transport system, and brain uptake suggests need for continued research.	Consider coadministration with close supervision and regular monitoring.
Levothyroxine Thyroid hormones ⊕⊕	L-Tyrosine is a precursor in endogenous synthesis of L-thyroxine. Additive interaction is probable from concomitant administration of exogenous thyroid hormone(s) and tyrosine, but possibly with minimal effect in individuals whose thyroid gland has atrophied from chronic use of synthetic thyroid medication. Adverse effects improbable. Research with well-designed trials examining various permutations warranted.	Coadministration may be beneficial. Monitor and titrate.
Monoamine oxidase (MAO) inhibitors ✗✗✗	MAO inhibitors can potentiate sympathomimetic substances and related compounds to induce a hypertensive crisis with potential risk of heart attack or stroke. Tyramine from food sources is usually implicated in such interactions, but tyramine can also be produced by intestinal bacteria from tyrosine through decarboxylation. This plausible but potentially dangerous interaction has not been confirmed by evidence from case reports or clinical trials.	Avoid concomitant use, also L-tryptophan, 5-HTP, and phenylalanine.
Oral contraceptives (OCs) ◈≈≈/≈≈/☼	Through effects on amino acid balance, exogenous estrogen and progestins can decrease plasma tyrosine levels, alter neurotransmitter levels, and potentially contribute to or exacerbate OC adverse effects, such as depression. Human research is limited and inadequate to determine occurrence of clinically relevant interactions or susceptibility factors. Adverse effects from coadministration improbable. Research with well-designed trials warranted.	Coadministration, with B-complex vitamins, may be beneficial unless otherwise contraindicated. Consider support for liver conjugation functions. Supervise and monitor.

5-HTP, 5-Hydroxytryptophan.

NUTRIENT DESCRIPTION

Physiology and Function

Tyrosine is a conditionally essential amino acid normally synthesized from phenylalanine, which is an essential amino acid. Hepatic conversion of L-phenylalanine to L-tyrosine can be impaired during infection, trauma, chronic illness, liver disease, or other forms of severe stress, thus making tyrosine a conditionally essential amino acid.

L-Tyrosine plays a critical role in the synthesis of neurotransmitters within the central nervous system (CNS). In particular, it serves as a precursor to L-dopa, dopamine, norepinephrine, and epinephrine, the brain concentrations of which depend on intake of tyrosine. The conversion of L-tyrosine into these neurotransmitters requires vitamin B_6, folic acid, and copper. Tyrosine also requires biopterin (a folate derivative), NADPH and NADH (metabolites of niacin), copper, and vitamin C. Tyrosine acts as an adaptogen through its role as a precursor of norepinephrine and epinephrine.

Several other key activities are among the known functions of tyrosine. Tyrosine is a precursor to thyroid hormones and catecholestrogens, compounds that have estrogen-like and catecholamine-like effects, as well as a constituent of amino sugars and amino lipids. It is also involved in the synthesis of enkephalins, important endogenous analgesic peptides in the endorphin family, and melanin, a pigment responsible for hair and skin color. Lastly, tyrosine binds free radicals and is considered a mild antioxidant.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Common uses include depression, thyroid nutriture, and alcohol withdrawal support. Individuals with phenylketonuria (PKU) are often treated with tyrosine to compensate for inborn errors of phenylalanine metabolism and resultant tendency to tyrosine deficiency.

Historical/Ethnomedicine Precedent

Tyrosine has not been used historically as an isolated nutrient.

Possible Uses

Addictions, alcohol withdrawal support, Alzheimer's disease, attention deficit disorder, cardiovascular disease, chronic fatigue, cocaine abuse and withdrawal, cognitive enhancement, dementia, depression, excessive appetite, fatigue, hypotensive crisis, hypothyroidism, impotence, jet lag, low libido, narcolepsy, Parkinson's disease, premenstrual syndrome, schizophrenia, stress disorders, weight loss.

Deficiency Symptoms

Because tyrosine is a precursor to thyroid hormones and catecholamines, a deficiency may lead to impaired thyroid function as well as low adrenal function. Some research indicates that tyrosine levels may be low in some individuals with depression. A lack of melanin caused by a tyrosine deficiency could predispose a person to skin cancer. Anyone experiencing a pattern of protein loss, especially over an extended period (e.g., with nephrotic syndrome), may develop a deficiency in tyrosine and other amino acids.

Dietary Sources

Dietary sources richest in tyrosine are fish, meat, dairy, eggs, nuts, wheat germ, and oats. Normally, tyrosine can be synthesized endogenously from L-phenylalanine.

Source of Supplemental Form

Most L-tyrosine in nutraceuticals is produced by bacterial fermentation processes in a growth medium, from which the amino acid is then purified.

Supplemental Form

Capsule, powder, tablet; solution, oral.

Tyrosine is best absorbed when ingested at least 30 minutes before meals, divided into three daily doses. Some manufacturers have claimed that acetyl-L-tyrosine (ALT) affects the brain more rapidly than any other form.

It is often recommended that tyrosine be taken together with a multivitamin-mineral complex because vitamins B_6, folate, and copper participate in the conversion of L-tyrosine into neurotransmitters.

Dosage Range

Adult

Dietary:

Recommended dietary intake (RDA): 7.3 mg/pound body weight/day, approximately 1 g/day
Average daily intake in United States: 3.5 to 5 g

Supplemental/Maintenance: Supplementation is usually not necessary for most individuals. Optimal levels of intake have not been established.
Pharmacological/Therapeutic: 1 to 8 g/day.

Clinical trials have used 100 mg/kg body weight/day, which constitutes a large dose. When indicated, many health care providers experienced in nutritional therapeutics initiate treatment with 2 g per day and gradually increase the dose as appropriate. Use at therapeutic doses would typically be short term. The most common recommended dose is 500 to 1000 mg three times daily (before each of the three meals).
Toxic: Usually not to exceed 12 g per day, the highest known safe level.

Pediatric (< 18 Years)

Dietary: No specific dietary recommendation has been established for tyrosine in children.
Supplemental/Maintenance: Not currently recommended for children.
Pharmacological/Therapeutic: Indicated when amino acid imbalance demonstrated by laboratory assessment. In particular, tyrosine is administered in patients with PKU once plasma tyrosine levels have been controlled. Other-wise, specific treatment recommendations have not been established.
Toxic: No toxic dosage level established specifically for infants and children.

Laboratory Values

Range of normal plasma tyrosine levels:

Children: 26 to 110 μmol/L
Adults: 45 to 74 μmol/L

SAFETY PROFILE

Overview

L-Tyrosine is usually tolerated well by most adults and generally considered to be free of adverse effects for most individuals at usual dosage levels of 2 to 3 g daily. L-Tyrosine has very low toxicity.

Nutrient Adverse Effects

General Adverse Effects

Nausea, diarrhea, vomiting, and nervousness are the primary effects associated with intake of high dosage levels of tyrosine in some reports. Migraine headache, elevated blood pressure, and mild gastric upset may also result from excessive levels of tyrosine (or tyrosine-derived neurotransmitters such as dopamine).

Adverse Effects Among Specific Populations

Use of tyrosine may be contraindicated for individuals with hyperthyroidism, Tourette's syndrome, or schizophrenia, particularly when high brain dopamine levels are present. Exogenous tyrosine (or phenylalanine) administration could theoretically result in elevated brain dopamine levels and symptom aggravation.

Exogenous tyrosine could theoretically promote cancer cell division in susceptible individuals. Many tumor cells overexpress tyrosine kinase enzymes; phosphorylated tyrosine functions as a cell-signaling molecule that drives DNA synthesis, cell growth, and division in these tumors.

Pregnancy and Nursing

Evidence is lacking within the scientific literature to suggest or confirm any adverse effects related to fetal development during pregnancy or to infants who are breast-fed associated with tyrosine administration. Caution still advised regarding supplementation with free-form L-tyrosine.

Infants and Children

No adverse effects have been reported. However, sufficient research-based evidence is lacking to guarantee the safety of tyrosine in infants and children.

Contraindications

Migraine.
L-Tyrosine is contraindicated in those with the inborn errors of metabolism, alkaptonuria and tyrosinemia types I and II.
Tyrosine (and phenylalanine) should be avoided by individuals with cancer, especially pigmented melanoma.
Tyrosine should be avoided by individuals taking monoamine oxidase (MAO) inhibitors because of its role in synthesis of dopamine, norepinephrine, and epinephrine.
L-Tyrosine is contraindicated in those hypersensitive to any component of an L-tyrosine-containing supplement.

Precautions and Warnings

Concomitant administration of phenylalanine and tyrosine at high dosage levels should be avoided outside of professional supervision due to potential additive effects. Food sources may contain both nutrients but typically would be considered safe at usual levels of intake.

INTERACTIONS REVIEW

Strategic Considerations

Tyrosine from direct dietary sources as well as that synthesized endogenously from phenylalanine provides adequate quantities for normal physiological functions in most healthy individuals with reasonable nutriture. Administration of tyrosine is uncommon in conventional medicine apart from prevention and treatment of tyrosine deficiency in individuals with PKU and occasionally as an adjunctive agent for individuals with Parkinson's disease. Oral dosage levels of 19.2 mg/kg daily, divided equally in meals, and 100 mg/kg daily in three divided doses are typical for PKU and Parkinson's patients, respectively. Prudent clinical management requires establishing controlled plasma tyrosine levels approximating the norm of 45 µmol/L before considering tyrosine administration. Furthermore, concomitant use of tyrosine and levodopa should be discouraged outside the context of medical supervision because levodopa may interfere with the absorption of tyrosine.

Although supportive evidence is largely inconclusive, many practitioners experienced in nutritional therapeutics routinely prescribe L-tyrosine, with other nutrients and botanicals, as part of a comprehensive strategy to support thyroxine, dopamine, and other neurotransmitters in the treatment of fatigue, depression, suboptimal thyroid function, and other conditions. Methods for establishing clinical indications and determining therapeutic response are largely anecdotal and unsystematic, with clinical research data limited and preliminary.

A review of the collective body of available evidence reveals several medications that may interact with tyrosine to produce clinically significant effects in certain patients. The potentially severe interaction with MAO inhibitors, including the risk of a hypertensive crisis and catastrophic sequelae, warrants a general contraindication of concomitant use. Physicians prescribing any of these medications should ask patients about supplemental use of tyrosine and advise that they be avoided or discontinued, except possibly under close supervision. However, most interactions involving tyrosine and conventional medications can be beneficial in appropriate circumstances, but usually warrant supervision, monitoring, and periodic adjustments. Thus, coadministration of tyrosine can often enhance clinical outcomes when used in conjunction with levodopa, levothyroxine, and oral contraceptives within an integrative strategy. Concomitant use with imipramine, mixed amphetamines, appetite suppressants, or opioid analgesics may be appropriate in some cases but requires close supervision and regular monitoring by health care providers trained and experienced in both conventional pharmacology and nutritional therapeutics. In many cases, tyrosine administration can work more effectively when complemented by folic acid, B vitamins, and other nutrients typically at suboptimal levels in the target patient populations, compromised with the primary pathology or comorbid conditions, depleted by typical medications, or otherwise supportive of the therapeutic intervention.

NUTRIENT-DRUG INTERACTIONS

Amphetamines and Related Stimulant Medications

Amphetamine (amphetamine aspartate monohydrate, amphetamine sulfate), dextroamphetamine (dextroamphetamine saccharate, dextroamphetamine sulfate, D-amphetamine, Dexedrine).
Methylphenidate (Metadate, Methylin, Ritalin, Ritalin-SR; Concerta).
Combination drug: Mixed amphetamines: amphetamine and dextroamphetamine (Adderall; dexamphetamine).
Extrapolated, based on similar properties: Modafinil (Provigil).
Related but no longer on market: Pemoline (Cylert).
See also Appetite-Suppressant Medications in Theoretical, Speculative, and Preliminary Interactions Research.

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**
≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**
☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **4. Plausible**
Evidence Base: **○ Preliminary**

Effect and Mechanism of Action

Both adrenergic stimulants and tyrosine have been used in the treatment of narcolepsy and attention deficit disorder (ADD) with hyperactivity. An increase in the availability of tyrosine, under certain conditions, may influence the synthesis and release of dopamine.

Research

Animal research indicates that tyrosine depletion attenuates the release of dopamine produced by amphetamine but not the release of noradrenaline. In a rodent model, Geis et al.[1] observed that rats exposed to amphetamines for 4 to 6 months, but not 35 days or less, reduced amphetamine self-administration after receiving tyrosine. These investigators hypothesized that tyrosine may be useful in certain individuals depending on their history of substance abuse. In an experiment using male rats, Woods and Meyer[2] reported that

exogenous tyrosine potentiates the methylphenidate-induced increase in extracellular dopamine in the nucleus accumbens.

A dietary deficiency of tyrosine may impair the therapeutic activity of amphetamines by depleting the available reserves of neurotransmitters. In an experiment involving 15 healthy volunteers, McTavish et al.[5] administered D-amphetamine (20 mg orally) 2 hours after they had ingested either a nutritionally balanced amino acid mixture or one lacking tyrosine and phenylalanine, the catecholamine precursors. These researchers observed that plasma tyrosine levels were significantly lower in subjects who received the nutrient-depleted mixture, but that mean plasma amphetamine levels were higher. Nevertheless, subjects reported that the nutrient-depleted mixture decreased the subjective psychostimulant effects of amphetamine, as indicated by visual analog scales. However, the nutrient-depleted mixture failed to reduce the subjective anorectic effect of amphetamine. This attenuation of some subjective effects of amphetamine after tyrosine depletion suggests that adequate tyrosine intake from dietary protein or nutraceuticals is essential to achieve full therapeutic effect in individuals administered amphetamines. Further research through large, well-designed clinical trials may be warranted.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing mixed amphetamines or related stimulants may consider coadministering L-tyrosine as part of an integrative therapeutic strategy. The potential therapeutic efficacy of either therapy may be enhanced by concomitant use, especially in individuals susceptible to or exhibiting a tyrosine deficiency. Prudent clinical management warrants supervision and regular monitoring within the context of collaborative care by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics.

Imipramine and Related Tricyclic Antidepressants (TCAs)

Evidence: Imipramine (Janimine, Tofranil).
Extrapolated, based on similar properties: Amitriptyline (Elavil); combination drug: amitriptyline and perphenazine (Etrafon, Triavil, Triptazine); amoxapine (Asendin), clomipramine (Anafranil), desipramine (Norpramin, Pertofrane), doxepin (Adapin, Sinequan), nortriptyline (Aventyl, Pamelor), protriptyline (Vivactil), trimipramine (Surmontil).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
4. Plausible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action:

L-Tyrosine functions as a precursor to L-dopa, dopamine, norepinephrine, and epinephrine, the brain concentrations of which depend on intake of tyrosine. Augmenting tyrosine intake may produce an additive effect.

Research

Chronic cocaine use is believed to cause catecholamine depletion, and similarities exist between cocaine withdrawal and major depression. Tyrosine is the dietary precursor to catecholamines, and administration has produced positive outcomes in small trials of its antidepressant efficacy. The synaptic loss of dopamine with cocaine abuse increases demands for dopamine synthesis, as evidenced by the increase in tyrosine hydroxylase activity after cocaine administration. Consequently, a dopamine deficiency develops when precursor reserves are exhausted. Administration of the precursors of the depleted monoamine neurotransmitters L-tyrosine and L-tryptophan is postulated to promote their biosynthesis and thus restore neurotransmitter function. Precursors use a naturally regulated pathway in which the precursor is converted to the neurotransmitter only when needed, and then the body distributes the product on the basis of need. As dopamine is synthesized from precursors such as L-tyrosine, dopamine reserves are rebuilt, thus overcoming the dopamine depletion problem. Thus, a benefit in treating drug dependence has been hypothesized based on these premises as well as the possibility of reducing the severe depression that typically accompanies withdrawal. Acute and chronic amphetamine abuse presents a situation analogous to that associated with cocaine abuse.

Human studies investigating the use of tyrosine, alone or with tryptophan, in the treatment of cocaine addiction and withdrawal have arrived at mixed conclusions.[4,7] However, in one small study the combination of imipramine, tyrosine, and tryptophan was associated with a success rate greater than 74% in the treatment of chronic cocaine abuse.[8] Verebey and Gold[9] proposed a regimen involving concomitant administration of L-tyrosine, L-tryptophan, thiamine, riboflavin, niacin, pantothenic acid, pyridoxamine, ascorbic acid, folic acid, and cyanocobalamin for the treatment of cocaine addiction. Further research through large, well-designed clinical trials may be warranted.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Health care professionals treating individuals for cocaine abuse may consider supporting the withdrawal process through administration of key neurotransmitter precursors such as tyrosine and tryptophan, possibly in concert with imipramine. Although not yet validated by mature research or conclusive evidence, such concomitant administration of these agents may be therapeutically appropriate within the context of collaborative care by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics and with close supervision and regular monitoring. Titration of medication dosage may be appropriate with significant therapeutic response to tyrosine; a tyrosine-induced excess is improbable.

Levodopa and Related Antiparkinsonian Medications

Evidence: Levodopa (L-dopa; Dopar, Larodopa).
Extrapolated, based on similar properties: Carbidopa (Lodosyn); levodopa combination drugs: levodopa and benserazide (co-beneldopa; Madopar); levodopa and carbidopa (Atamet, Parcopa, Sinemet, Sinemet CR); levodopa, carbidopa, and entacapone (Stalevo).

Effect and Mechanism of Action
L-Tyrosine is a semi-essential amino acid that converts to L-dopa (levodopa), and administration of tyrosine can increase dopamine levels. However, levodopa may interfere with the absorption of tyrosine by competitively inhibiting the transport system.[10] Furthermore, levodopa and aromatic amino acids such as tyrosine and tryptophan can compete for brain uptake, and simultaneous administration may decrease levels of both nutrients and the medication.[11]

Research
Tyrosine has been considered a potential tool in the treatment of Parkinson's disease, depression, and other related conditions based on its role as a neurotransmitter precursor. Rodent and human studies have demonstrated that L-tyrosine administration can enhance dopamine synthesis. Growdon et al.[12] measured levels of tyrosine and homovanillic acid, the major dopamine metabolite, in lumbar cerebrospinal fluid (CSF) of 23 patients with Parkinson's disease before and during ingestion of 100 mg/kg/day of tyrosine; nine subjects were coadministered 100 mg/kg/day of probenecid (to prolong half-life of tyrosine by slowing renal elimination) in six divided doses for 24 hours before each spinal tap, whereas the other 14 did not receive probenecid. These researchers observed that CSF tyrosine levels significantly increased in both groups after oral L-tyrosine administration, and that homovanillic acid levels significantly increased in the group of patients pretreated with probenecid. These findings indicate that "L-tyrosine administration can increase dopamine turnover in patients with disorders in which physicians wish to enhance dopaminergic neurotransmission."[12]

In a small preliminary trial, Lemoine et al.[13] prescribed L-tyrosine (45 mg/lb body weight) to five naive patients diagnosed after sleep polygraphy criteria and five patients receiving L-dopa and/or dopamine agonist as long-term treatment of Parkinson's disease. After 3 years of L-tyrosine treatment, several patients demonstrated better clinical results and significantly fewer adverse effects than subjects treated with L-dopa or dopamine agonists. These authors cautioned that further research would be required to determine the "theoretical long-term sparing neurons potentiality" of this approach.

Riederer[11] spectrofluorometrically assayed tyrosine and tryptophan in postmortem human brain areas of patients with Parkinson's disease treated orally with or without L-dopa plus the peripherally acting decarboxylase inhibitor benserazide. He observed that both tyrosine and tryptophan were significantly decreased after treatment with L-dopa and interpreted these findings as demonstrating a competitive action of L-dopa to other aromatic amino acids on human brain uptake. No research has been conducted to determine whether such depletion is clinically significant. Furthermore, evidence is lacking as to whether concomitant L-tryosine could prevent or reverse adverse effects, if any, and whether such coadministration would be safe and effective. Well-designed clinical trials are warranted.

Nutritional Therapeutics, Clinical Concerns, and Adaptations
Administration of L-tyrosine, or its precursor phenylalanine, may serve as a valuable adjunctive therapy in the treatment of Parkinson's disease or similar conditions. Coadministration of tyrosine may prevent or reverse nutrient depletion resulting from levodopa therapy. However, concomitant use of levodopa and L-tyrosine could introduce several complications and should be avoided except under close supervision, regular monitoring, and coordinated care by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics. Although concomitant administration might enhance effectiveness and reduce adverse effects of levodopa therapy, it carries an attendant risk of inducing adverse effects by excessively elevating dopamine levels. In cases where tyrosine is indicated, ingestion of the two agents should be separated (e.g., at least 4 hours apart) to reduce interference with absorption and CNS uptake.

Levothyroxine and Related Thyroid Hormones

L-Triiodothyronine (T_3): Cytomel, liothyronine sodium, liothyronine sodium (synthetic T_3), Triostat (injection).
Levothyroxine (T_4): Eltroxin, Levo-T, Levothroid, levothyroxine (synthetic), levoxin, Levoxyl, Synthroid, thyroxine, Unithroid.
L-Thyroxine and L-triiodothyronine (T_4 + T_3): animal levothyroxine/liothyronine, Armour Thyroid, desiccated thyroid, Westhroid.
L-Thyroxine and L-triiodothyronine (synthetic T_4 + T_3): Euthroid, Euthyral, liotrix, Thyar, Thyrolar.
Dextrothyroxine (Choloxin).

Interaction Type and Significance
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable or
1. Certain
Evidence Base:
☐ **Inadequate,** but considered
● **Consensus**

Effect and Mechanism of Action
L-Tyrosine is a direct precursor to thyroxine. Coadministration of tyrosine and exogenous thyroid hormone(s) may produce an additive interaction.

Research
Evidence from clinical trials directly investigating coadministration of tyrosine and thyroid hormone is lacking. Nevertheless, the effect of tyrosine levels on thyroid function is considered axiomatic within conventional pharmacology. Physicians experienced in nutritional therapeutics report beneficial effects after administering tyrosine to support thyroid function and coadministering tyrosine with various forms of exogenous thyroid hormone in treating individuals with hypothyroidism.

Nutritional Therapeutics, Clinical Concerns, and Adaptations
With proper clinical management, coadministration of tyrosine with natural or synthetic thyroid medications represents a potentially valuable synergy in the treatment of individuals with subclinical or frank hypothyroid conditions. The administration of tyrosine, alone or in combination with synergistic

agents such as iodine, is common within the professional practice of nutritional therapeutics. Concomitant administration of tyrosine may be therapeutically appropriate but requires supervision and regular monitoring within the context of collaborative care by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics. Titration of medication dosage may be appropriate with significant therapeutic response to tyrosine; a tyrosine-induced hyperthyroid state is improbable. Conversely, any additive effect of augmented tyrosine intake may be minimal in individuals whose thyroid gland has atrophied because of chronic use of synthetic thyroid medication and subsequent decline in endogenous hormone synthesis.

Monoamine Oxidase (MAO) Inhibitors

MAO-A inhibitors: Isocarboxazid (Marplan), moclobemide (Aurorix, Manerix), phenelzine (Nardil), procarbazine (Matulane), tranylcypromine (Parnate).
MAO-B inhibitors: Rasagiline (Azilect), selegiline (deprenyl, L-deprenil, L-deprenyl; Atapryl, Carbex, Eldepryl, Jumex, Movergan, Selpak).

Interaction Type and Significance

✗✗✗ **Potentially Harmful or Serious Adverse Interaction—Avoid**

Probability: **2. Probable**
Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

The MAO inhibitors act by inhibiting the activity of the enzyme monoamine oxidase, which normally breaks down central monoamine neurotransmitters to render them inactive. The potentiation of sympathomimetic substances and related compounds by MAO inhibitors may result in hypertensive crisis and potential risk of heart attack or stroke. Tyramine in foods (e.g., red wine, aged cheeses) is the pressor amine most often implicated in these reactions. Tyrosine is converted into tyramine through decarboxylation by bacteria in the bowel. Therefore, elevated levels of tyrosine could induce an increase in tyramine capable of causing a clinically significant interaction.

Research

Concomitant intake of an MAO inhibitor (including selegiline) and foods containing certain pressor amines, particularly tyramine, or pharmacological agents containing sympathomimetic agents, has been associated with potentially serious hyperadrenergic states.[14] Besides tyramine, other amines and amine precursors, such as tyrosine, dopamine, levodopa, and histamine, may also precipitate such interactions.[15] This interaction is severe but infrequent and is characterized by severe occipital and temporal headache, elevation of both systolic and diastolic blood pressures, neuromuscular excitation, neck stiffness, diaphoresis, and mydriasis, generally occurring within 2 hours of ingestion of the substances. Cardiac dysrhythmias, heart failure, or intracerebral hemorrhage can occur, but rarely do. Meperidine (Demerol) and dextromethorphan (in many OTC cough medicines) have both been associated with fatal interactions with the type A MAO inhibitors.

Reports

No case reports have been published documenting adverse interactions involving tyrosine and MAO inhibitors. However, several reports have described delirium, hypomania, myoclonus, hyperreflexia, and diaphoresis attributed to the combination of L-tryptophan and a MAO inhibitor.[16-18]

Clinical Implications and Adaptations

Physicians prescribing phenelzine and related MAO inhibitors need to advise patients to avoid concomitant intake of L-tyrosine, sympathomimetic drugs (including amphetamines, cocaine, methylphenidate, dopamine, epinephrine, and norepinephrine), or related compounds (including methyldopa, L-dopa, L-tryptophan, 5-HTP, and phenylalanine), as well as foods high in tyramine. Concomitant administration of tyrosine may be appropriate in the treatment of some individuals but requires close supervision and regular monitoring within the context of collaborative care by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics.

Oral Contraceptives: Monophasic, Biphasic, and Triphasic Estrogen Preparations (Synthetic Estrogen and Progesterone Analogs)

Ethinyl estradiol and desogestrel (Desogen, Ortho-TriCyclen).
Ethinyl estradiol and ethynodiol (Demulen 1/35, Demulen 1/50, Nelulen 1/25, Nelulen 1/50, Zovia).
Ethinyl estradiol and levonorgestrel (Alesse, Levlen, Levlite, Levora 0.15/30, Nordette, Tri-Levlen, Triphasil, Trivora).
Ethinyl estradiol and norethindrone/norethisterone (Brevicon, Estrostep, Genora 1/35, GenCept 1/35, Jenest-28, Loestrin 1.5/30, Loestrin1/20, Modicon, Necon 1/25, Necon 10/11, Necon 0.5/30, Necon 1/50, Nelova 1/35, Nelova 10/11, Norinyl 1/35, Norlestin 1/50, Ortho Novum 1/35, Ortho Novum 10/11, Ortho Novum 7/7/7, Ovcon-35, Ovcon-50, Tri-Norinyl, Trinovum).
Ethinyl estradiol and norgestrel (Lo/Ovral, Ovral).
Mestranol and norethindrone (Genora 1/50, Nelova 1/50, Norethin 1/50, Ortho-Novum 1/50).
Related, Internal Application: Etonogestrel/ethinyl estradiol vaginal ring (Nuvaring).

Interaction Type and Significance

◈≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**
≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**
☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **2. Probable**
Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

The formation of brain noradrenaline depends on brain tyrosine levels, associated with the ratio in plasma of tyrosine to other large, neutral amino acids (LNAAs). The combination of estrogen and progestins in oral contraceptives (OCs) can decrease plasma levels of tyrosine so as to contribute to adverse effects of the medications (e.g., depression).

Research

Moller and colleagues have been investigating the effects of OC use on amino acid metabolism for more than 25 years. In 1981, they studied the relationship of this effect on tryptophan and tyrosine, in particular on the association between OC

use and depression. They found that, compared to controls, the "estrogen-progestogen users showed elevated plasma levels of total tryptophan and decreased levels of tyrosine," and that there "was a clear trend that the incidence of adverse reactions was related to the decrease in tyrosine levels." Furthermore, "the plasma ratio of tryptophan to competing amino acids was increased in the estrogen-progestogen users, whereas the ratio of tyrosine to competitors was severely decreased suggesting a decreased brain tyrosine concentration." They noted that ethinyl estradiol was more potent than mestranol in its effect on plasma tyrosine.[19] In a subsequent series of published human studies, they demonstrated significantly increased plasma tyrosine transaminase activity, and significantly decreased plasma tyrosine and tyrosine/LNAA levels at midcycle and luteal phase, relative to the follicular phase, in women administered new-generation combined OCs compared with comparable controls. They observed that, after an oral protein load, the area under the curve in plasma of tyrosine and tyrosine/LNAA in OC users at the luteal phase were 43% and 29%, respectively, of control levels. These results "suggest that the decreased tyrosine availability to the brain in OC users may result in a substrate-limited reduction of brain noradrenaline formation, which, secondarily, may contribute to disturbances of mood, coping mechanisms, and appetite in susceptible subjects."[20] These researchers interpreted the findings of their third study to "suggest that the metabolic effects of the new-generation combined OCs on neutral amino acids and cholesterol are only modest to slight, except for the effect on tyrosine, the brain noradrenaline precursor, which may cause disturbances of various noradrenaline-mediated central functions in susceptible individuals."[21]

Clinical Implications and Adaptations

Physicians prescribing OCs may find it prudent to suggest that patients supplement with L-tyrosine and B-complex vitamins, particularly if they are susceptible to or have experienced depression or other emotional adverse effects in relation to medication use. Botanical and nutrient support of liver conjugation may also be beneficial within the context of collaborative care by health care professionals trained and experienced in both conventional pharmacology and nutritional/botanical therapeutics. Such coadministration is generally considered safe and does not require regular monitoring.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Appetite-Suppressant Medications, Including Amphetamine, Ephedrine, and Phenylpropanolamine

See also Amphetamines and Related Stimulant Medications.

As a precursor of many neurotransmitters, tyrosine may increase the activity of exogenous sympathomimetic agents. In an animal model using hyperphagic rats, Hull and Maher[22] observed that L-tyrosine (200 and 400 mg/kg) potentiated the anorectic activity of amphetamine/AMPH (0.75, 1.25, or 1.75 mg/kg), ephedrine/EPH (5, 10, or 20 mg/kg), and phenylpropanolamine/PPA (5, 10, or 20 mg/kg) in a dose-dependent manner. This response pattern suggested increased catecholamine synthesis in stimulated neurons. Notably, the potentiation by L-tyrosine was attenuated when L-valine was coadministered. However, in a subsequent experiment, they found that L-tyrosine fails to potentiate several peripheral actions of the sympathomimetics, particularly peripherally mediated PPA-, EPH-, and AMPH-induced increases in gastrointestinal transit time and retention and intrascapular brown adipose tissue thermogenesis. Lastly, these researchers demonstrated that although each of the mixed-acting sympathomimetics significantly increased mean arterial, systolic, and diastolic blood pressures when administered alone, the coadministration of L-tyrosine failed to potentiate the pressor responses of PPA, EPH, or AMPH in urethane-anesthetized rats. Thus, Hull and Maher[23] concluded that the potentiation of the mixed-acting sympathomimetics by L-tyrosine is "largely restricted to centrally mediated responses."

Research through well-designed clinical trials would be necessary to determine whether coadministration of L-tyrosine and sympathomimetic appetite-suppressant agents would produce similar results in humans. Even though pharmacologically plausible, the combined use of these agents cannot be supported by the available evidence.

Codeine, Methadone, Morphine, and Related Oral Narcotic Analgesics (Opiates)

Butorphanol (Stadol, Stadol NS), codeine sulfate, fentanyl (Actiq Oral Transmucosal, Duragesic Transdermal, Fentanyl Oralet, Sublimaze Injection), hydrocodone, hydromorphone (Dilaudid), levorphanol (Levo-Dromoran), meperidine (Demerol), methadone (Dolophine, Methadose), methadone hydrochloride (Dolophine, Methadose), morphine sulfate (Astramorph PF, Avinza, Duramorph, Infumorph, Kadian, MS Contin, MSIR, Oramorph SR, RMS; Roxanol, Roxanol Rescudose, Roxanol T), opium tincture, oxycodone (Endocodone, OxyContin, OxyIR, Percolone, Roxicodone), oxymorphone (Numorphan), paregoric, pentazocine (Talwin, Talwin NX), propoxyphene (Darvon; Darvon-N).

Combination drugs: Buprenorphine and naloxone (Suboxone); codeine and acetaminophen (Capital and Codeine; Phenaphen with Codeine; Tylenol with Codeine); codeine and acetylsalicylic acid (Empirin with codeine); codeine, acetaminophen, caffeine, and butalbital (Fioricet); codeine, acetylsalicylic acid, caffeine, and butalbital (Fiorinal); hydrocodone and acetaminophen (Anexsia, Anodynos-DHC, Co-Gesic, Dolacet, DuoCet, Hydrocet, Hydrogesic, Hy-Phen, Lorcet 10/650, Lorcet-HD, Lorcet Plus, Lortab, Margesic H, Medipain 5, Norco, Stagesic, T-Gesic, Vicodin, Vicodin ES, Vicodin HP, Zydone); hydrocodone and acetylsalicylic acid (Lortab ASA); hydrocodone and ibuprofen (Reprexain, Vicoprofen); opium and belladonna (B&O Supprettes); oxycodone and acetaminophen (Endocet, Percocet 2.5/325, Percocet 5/325, Percocet 7.5/500, Percocet 10/650, Roxicet 5/500, Roxilox, Tylox); oxycodone and acetylsalicylic acid (Endodan, Percodan, Percodan-Demi); pentazocine and acetaminophen (Talacen); pentazocine and acetylsalicylic acid (Talwin Compound); propoxyphene and acetaminophen (Darvocet-N, Darvocet-N 100, Pronap-100, Propacet 100, Propoxacet-N, Wygesic); propoxyphene and acetylsalicylic acid (Bexophene, Darvon Compound-65 Pulvules, PC-Cap); propoxyphene, acetylsalicylic acid, and caffeine (Darvon Compound).

Research using a rodent model indicates that L-tyrosine may potentiate the analgesic effect of opiate medications. In an experiment exposing rodents to a hot plate, Hull et al.[24] found that the observed potentiation of morphine sulfate (10 mg/kg) and codeine sulfate (30 mg/kg) was positively correlated with increases in brain tyrosine concentrations. The L-tyrosine-induced potentiation was dependent on increased catecholamine synthesis, as determined by alpha-methyl-*p*-tyrosine pretreatment. Furthermore, blockade of L-tyrosine uptake into the brain by the coadministration of L-valine attenuated this potentiation. No other L-amino acid, except

L-tryptophan, was capable of mimicking the potentiating action of L-tyrosine. The authors concluded that these findings demonstrate that L-tyrosine "dose dependently potentiates the analgesic activity of opioids and are consistent with the requirement of the central conversion of L-TYR to catecholamines via TYR hydroxylase for this response."[24] In a subsequent study, Ali[25] observed that L-tyrosine (25, 50, 100, and 200 mg/kg), administered subcutaneously, dose-dependently potentiated the antinociceptive action of subcutaneous morphine (5 mg/kg).

Well-designed clinical trials would be necessary to determine whether L-tyrosine would potentiate the analgesic activity of opiates in humans.

NUTRIENT-NUTRIENT INTERACTIONS

5-Hydroxytryptophan (5-HTP)

Tyrosine levels are occasionally low in depressed patients. Several studies in the 1970s published encouraging findings showing potential benefit from the treatment of depression using tyrosine, especially when combined with 5-HTP.[26-29] However, subsequent research failed to demonstrate significant antidepressant activity on the part of L-tyrosine.[30] Further human trials are warranted to investigate the relative influences of variations in presentations of depression, associated neurotransmitter patterns, and pharmacogenomic variability, as well as practice management principles for shaping individualized and evolving therapeutic interventions.

Branched-Chain Amino Acids: Isoleucine, Leucine, Valine

Branched-chain amino acids (BCAAs: isoleucine, leucine, valine) compete with tyrosine and other aromatic amino acids for absorption and transport across the blood-brain barrier into the brain. Separating intake of tyrosine (by at least 2 hours) from other amino acids and meals high in protein will reduce interference with bioavailability and therapeutic action. Dietary carbohydrates increase the amount of tryptophan, tyrosine, and phenylalanine that reach the brain.

Iodine

L-Tyrosine is a direct precursor to thyroxine. The combined use of tyrosine and iodine, from dietary or supplemental sources, has been practiced within naturopathic medicine and other traditions of nutritional therapeutics for decades, based on the hypothesis that coordinated intake can support the endogenous synthesis of thyroid hormones. Nevertheless, evidence from clinical trials directly investigating coadministration of tyrosine and iodine is lacking. Long-term, well-designed clinical trials are warranted to determine the safety and efficacy of this therapeutic strategy.

Phenylalanine

L-Tyrosine is synthesized from L-phenylalanine. Coadministration could theoretically enhance the activity of both nutrients. However, concomitant administration of phenylalanine and tyrosine at high dosage levels should be avoided outside of professional supervision because of potential additive effects. Food sources may contain both nutrients but typically would be considered safe at usual levels of intake.

The 30 citations for this monograph, as well as additional reference literature, are located under Tyrosine on the CD at the back of the book.

5-Hydroxytryptophan

Nutrient Name: 5-Hydroxytryptophan.
Synonyms: 5-HTP, L-5-hydroxytryptophan, L-5-HTP.
Related Substances: L-tryptophan; 5-hydroxytryptamine, 5-HT, serotonin.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
D-Amphetamine Stimulant medications ⊕/☼	5-Hydroxytryptophan (5-HTP) may mitigate adverse effects associated with amphetamine therapy in schizophrenic patients through an unknown mechanism.	Concomitant use could be therapeutic with appropriate clinical management.
Carbidopa Antiparkinsonian medications ⊕⊕/⊕✗/✗✗	Coadministration of 5-HTP with carbidopa therapy may reduce attention myoclonus and related neuromuscular disorders by enhancing serotonin levels. Some individuals react with symptoms that include scleroderma-like lesions, based on enzyme variability.	Concomitant use could be therapeutic with appropriate clinical management and attention to individual pharmacogenomic response.
Chlorimipramine Tricyclic antidepressants ⊕/⊕✗/✗✗	Coadministration of chlorimipramine and 5-HTP can elevate serotonin and cortisol levels, possibly producing more favorable therapeutic response in treatment of depression than either agent alone; additive effects of concomitant use could be detrimental or beneficial, depending on clinical circumstances.	Concomitant use could be therapeutic or detrimental. Individualized assessment, flexible clinical management, close supervision, and regular monitoring required.
Lithium ⊕⊕/☼	Lithium may enhance 5-HTP-induced increase in serum cortisol concentration in bipolar or depressed patients. Concomitant administration of 5-HTP may improve clinical outcomes, especially in patients resistant to lithium therapy alone.	Concomitant use could be therapeutic, if indicated. Individualized assessment, close supervision, and regular monitoring required.
Sertraline Selective serotonin reuptake inhibitor (SSRI) antidepressants ✗✗✗/⊕✗/⊕	As a 5-HT precursor, 5-HTP administration can elevate serotonin levels. SSRIs inhibit serotonin uptake. Probable additive effect from combined use of these agents appears to be near-certain with adverse interactions of rapid onset and severe character, particularly serotonin syndrome. However, direct evidence from clinical trials or case reports is minimal, if not absent. Closely supervised coadministration suggested in select circumstances, but supportive evidence lacking and currently outweighed by suspected risks.	Avoid concomitant use because of probable risks.
Selegiline Monoamine oxidase (MAO-B) inhibitors ⊕⊕/⊕✗/✗	Small clinical trials indicate that coadministration of 5-HTP with selegiline in treatment of unipolar and bipolar depression may enhance MAO inhibition and clinical response through additive effect on serotonin.	Concomitant use could be therapeutic, if indicated. Individualized assessment, close supervision, and regular monitoring required.
Sibutramine Serotonin agonists ✗✗✗	As a 5-HT precursor, 5-HTP administration can elevate serotonin levels. As a serotonin agonist, sibutramine inhibits serotonin uptake. Probable additive effect from combined use of these agents induces significant risk of adverse interactions of rapid onset and severe character, particularly serotonin syndrome. However, direct evidence from clinical trials or case reports is minimal, if not absent.	Avoid concomitant use because of probable risks.
Sumatriptan, zolmitripton Triptans ✗✗✗	As a 5-HT precursor, 5-HTP administration can elevate serotonin levels. As serotonin receptor agonists (5-HT1B/1D), triptans bind to and activate serotonin receptors. Probable additive effect from combined use of these agents induces significant risk of adverse interactions of rapid onset and severe character, particularly serotonin syndrome. However, direct evidence from clinical trials or case reports is minimal, if not absent.	Avoid concomitant use because of probable risks.

NUTRIENT DESCRIPTION

Chemistry and Form

5-hydroxytryptophan (5-HTP) is similar in structure to tryptophan except that an OH group has been added to the fifth group of the carbon ring. Subsequently, the amino acid decarboxylase enzyme converts 5-HTP to 5-hydroxytryptamine (5-HT, serotonin).

Physiology and Function

Within the human body, the amino acid L-tryptophan is converted into 5-HTP. Tryptophan is one of eight essential amino acids that must be obtained from the diet. Its primary functions include its role in niacin (vitamin B_3) synthesis and as a precursor to both serotonin and melatonin. Approximately 98% of dietary L-tryptophan is metabolized into nicotinic acid (niacin), and only a very small amount is metabolized into serotonin via the intermediary stage of 5-HTP. 5-Hydroxytryptamine (5-HT, serotonin) is a key neurotransmitter associated with sleep, mood, aggression, anxiety, locomotion, body temperature, feeding, and pain sensation. The central serotoninergic neuronal system is quite complex. Seven discrete major serotonin receptors, numbered 1 through 7, have been characterized; several of these have been further divided into A, B, and C subtypes. Each of these receptors binds serotonin, various drugs, and other ligands with varying avidity, and several of these serotonin receptor subtypes have functionally opposing roles, notably the effects of 5-HT1A

and 5-HT2C receptor agonism on anxiety. The potent nausea-blocking agents used with many cancer chemotherapies specifically block the 5-HT3 receptor. The neuroendocrine effects of 5-HTP appear to be mediated through 5HT2A/5HT2C receptors.

5-Hydroxytryptophan crosses the blood-brain barrier (BBB, through a calcium-dependent mechanism) and affects hypothalamic-pituitary-adrenal activity by stimulating the central nervous system (CNS) synthesis and release of serotonin. Serotonin is synthesized in the CNS and gut using the unique indole moiety of tryptophan as its nucleus. Serotonergic neurons express the enzyme *tryptophan hydroxylase* (TPH), which catalyzes the conversion of tryptophan to 5-hydroxytryptophan. TPH is the rate-limiting biosynthetic enzyme in the serotonin pathway; it regulates levels of serotonin and is normally only about half-saturated. Serotonin is formed from tryptophan in a two-step process: after formation of 5-HTP by TPH, the final decarboxylation is catalyzed by aromatic L-amino acid decarboxylase (AADC), resulting in the conversion of 5-HTP to 5-HT (serotonin). The pineal gland is the major site for synthesis of *melatonin*, a methoxy derivative of tryptophan that modulates the sleep cycle, among other activities. The pineal gland also synthesizes serotonin, production of which is upregulated at night and controlled by beta-adrenergic signaling. Serotonin is present at highest concentrations in platelets and in the gastrointestinal (GI) tract. Lesser amounts are found in the brain and the retina. Serotonin in the CNS is metabolized by the monoamine oxidase (MAO) enzyme to 5-hydroxyindoleacetic acid (5-HIAA). Levels of 5-HIAA in cerebrospinal fluid (CSF) are believed to reflect serotonergic activity in the CNS. Urinary levels are probably a less precise reflection but may be clinically useful.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

5-Hydroxytryptophan is primarily used in the treatment of anxiety, depression, insomnia, and other conditions typically associated with serotonin deficiency or dysregulatory states. Poldinger et al.[1] argue that, although 5-HTP appears to be treating depression, it may actually be treating a much broader condition, "serotonin deficiency syndrome." This syndrome may manifest in any of a variety of forms, including depression, anxiety, sleeplessness, aggressiveness, agitation, obsessive-compulsive traits, migraines, and other common behavioral disorders.

5-Hydroxytryptophan is well absorbed, with approximately 70% of an oral dose reaching the bloodstream. Subsequently, some exogenous 5-HTP is rapidly decarboxylated in the peripheral vasculature to form serotonin, and the remainder crosses the BBB and increases synthesis of serotonin within serotonergic neurons. Therapeutic use of 5-HTP bypasses the conversion of L-tryptophan into 5-HTP by TPH, the rate-limiting step in the synthesis of serotonin.

Research using infusions of radiolabeled 5-HTP and positron-emission tomography (PET) scanning found that significantly less 5-HTP crossed the BBB into the brains of depressed subjects than into the brains of normal controls. Such findings have been interpreted to suggest that the transport of 5-HTP across the BBB may be compromised in major depression.

5-Hydroxytryptophan was introduced into the U.S. market in 1994. L-Tryptophan had been tarnished in the late 1980s and early 1990s by toxic effects of contaminated material produced by one Japanese supplier. In contrast, the related compound 5-HTP could be used for a therapeutically similar effect, but without the attendant susceptibility to contamination; 5-HTP is not produced by microbial biosynthesis requiring subsequent purification steps.

Historical/Ethnomedicine Precedent

5-Hydroxytryptophan has not been used historically as an isolated nutrient.

Possible Uses

Aggressive behavior, alcohol addiction, anxiety, attention deficit–hyperactivity disorder, bipolar disorder, bulimia, childhood headaches, depression, Down syndrome, fibromyalgia, hepatitis, insomnia, migraine, narcolepsy, obesity, obsessive-compulsive disorder, pain syndromes, Parkinson's disease, premenstrual syndrome, rheumatoid arthritis, schizophrenia, seasonal affective disorder, sleep apnea, sleep disorder–related headaches (children), sleep paralysis, systemic lupus erythematosus, tension headaches, Tourette's syndrome, weight management.

Deficiency Symptoms

Standard definitions of deficiency states have not been established, given endogenous synthesis, and because the relationship between 5-HTP status and serotonin-shortage syndrome is controversial. However, many clinicians and researchers have considered anxiety, depression, insomnia, and other conditions as deriving from diminished serotonin status and therefore implicitly some measure of 5-HTP deficiency.

Dietary Sources

Diets low in tryptophan may result in reduced synthesis of serotonin and melatonin, but L-tryptophan from dietary sources does not directly influence or contribute to 5-HTP levels.

Dosage Forms Available

Capsule, tablet; typically containing 25, 50, or 100 mg.

Source Materials for Nutrient Preparations

An alcoholic extraction process is used to extract 5-HTP from the seeds of the *Griffonia simplicifolia*, an African plant. The resulting oily solid is then purified into a dry solid at 99% or higher purity levels.

Dosage Range

Adult

Dietary: Not applicable per se.
Supplemental/Maintenance: 5-HTP is usually not taken except for therapeutic purposes.
Pharmacological/Therapeutic: Oral: 50 to 100 mg one to three times daily; occasionally, doses up to 200 mg three times daily may be appropriate. Doses of 100 to 200 mg daily may be effective for many individuals, and dosages used in clinical trials have ranged from 150 to 900 mg daily over 2 weeks to 6 months. Dosages are usually divided throughout the day, with possible increased dosage before bedtime; 5-HTP is often taken only before bedtime to enhance sleep. Orally administered 5-HTP is considered to provide the most rapid absorption when taken on an empty stomach.

Toxic: Excessive oral intake of 5-HTP could theoretically induce a state of serotonin excess, but levels necessary to exceed such a threshold have not been established and would most likely vary significantly among individuals based on health status, comorbid conditions, and pharmacogenomics.

Pediatric (< 18 Years)
Dietary: Not applicable per se.
Supplemental/Maintenance: 5-HTP is usually not taken except for therapeutic purposes.
Pharmacological/Therapeutic: Data are lacking on dosage for 5-HTP administration in children. Such usage is not recommended in sources reviewed.
Toxic: Data are lacking on toxicity of 5-HTP in children.

Laboratory Values

Serotonin may be relevant and could be assessed via urinary levels of 5-hydroxyindoleacetic acid (5-HIAA), the chief breakdown metabolite of serotonin.

SAFETY PROFILE

Overview

Individuals taking higher doses of 5-HTP have reported anxiety, digestive upset, headache, lethargy, and muscle pain, with GI symptoms being the most common. Theoretically, serotonin syndrome could result from use of excessive levels of 5-HTP, especially in combination with medications, herbs, or other supplements that alter serotonin levels or impair regulation. Some individuals with compromised liver function might not be able to regulate 5-HTP properly and require close medical supervision. Further, contaminants reported in some commercially available sources of 5-HTP may be associated with symptoms similar to eosinophilia-myalgia syndrome (EMS), which was linked to contaminated tryptophan in the late 1980s and early 1990s; however, recent reports of such incidents are lacking.

Nutrient Adverse Effects

Nausea and mild GI distress are the most common adverse effects generally associated with 5-HTP intake. Such GI symptoms affect only a minority of users, and then only occasionally. They usually lessen or disappear in the first few days or weeks of use. Headache, drowsiness, anxiety, and generalized muscle pain have also been reported. Research indicates that the incidence of such adverse reactions is minimal and usually only associated with higher dosage levels than typically used. Careful dose titration for each individual will usually prevent or minimize the occurrence of nausea and other adverse effects. Anecdotal clinical experience has suggested that, in patients very sensitive to GI effects of 5-HTP, a time-release preparation of 5-HTP from a compounding pharmacy will overcome this problem.

Adverse Effects Among Specific Populations

Individuals diagnosed with liver disease or compromised liver function may have limited capacity to metabolize 5-HTP and should avoid concomitant use with substances known to impair hepatic function or cause liver damage. Likewise, individuals with scleroderma or other autoimmune diseases may be more susceptible to an adverse reaction to 5-HTP intake; such cases also require consultation with a health care professional trained and experienced in prescribing physiologic agents such as 5-HTP.

Genotoxicity and Teratogenicity

Pregnancy and Nursing

The safety of exogenous 5-HTP intake during pregnancy and breastfeeding has not been established at this time.

Infants and Children

Data are lacking regarding toxicity and safety parameters for 5-HTP administration in infants and children. A high level of caution is suggested, especially given concerns of adverse effects among children receiving selective serotonin reuptake inhibitor (SSRI) therapy. Such pharmacological manipulation of serotonin levels and regulatory processes is generally not recommended, and significant caution is warranted, especially given the continued reports of adverse effects (and limited efficacy) in children being treated with conventional antidepressants, particularly SSRIs.[2]

Sparse anecdotal clinical evidence suggests that 5-HTP is well tolerated and can be effective as an alternative in children for whom experienced clinicians have recommended SSRI therapy for anxiety and depression, or in pervasive developmental disorders. In the absence of clinical trials, such therapy should be undertaken only by clinicians experienced in child psychiatry/psychology, in concert with clinicians experienced with 5-HTP and other nutraceutical therapies. SSRIs and 5-HTP may be hazardous to combine in both children and adults.

Contraindications

Because of the generally accepted risk of excessive serotonin levels and resultant effects, it is usually recommended that 5-HTP not be taken concomitantly with antidepressant medications (SSRIs, tricyclics, MAO-A inhibitors) or other serotonin-modifying agents. Given the rapid action of orally administered 5-HTP and the potentially high risk of complications, such concomitant administration should be avoided, except possibly under close supervision of and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional precursor therapeutics, preferably within the context of an inpatient research setting. Direct evidence of such adverse interactions is minimal, but caution is advisable.

Precautions and Warnings

It has occasionally been recommended that individuals with asthma avoid oral 5-HTP intake, based on the theory that the condition could be aggravated by elevating levels of any serotonin precursor, and that higher dosage levels in particular might increase the risk of exercise-induced asthma and fatigue. There is no substantial clinical evidence of this, but it should be kept in mind as a possibility, if a patient with underlying asthma were to experience exacerbation while taking 5-HTP. Given the pharmacokinetics involved, discontinuation of the 5-HTP should result in rapid resolution of the exacerbation, were this to occur.

Note: During the early 1990s a substance designated as "Peak X" was reportedly found in low concentrations in some 5-HTP preparations. Speculation arose that it might be linked to the EMS previously associated with contaminated batches of L-tryptophan, which contained larger amounts of "Peak X," although the exact structure of this component and a causative role in EMS were never definitively established. No substantive evidence ever confirmed a connection between this substance and alleged incidents of 5-HTP toxicity, nor was

it ever conclusively proven to have caused or contributed to any adverse events or toxicity reactions.

INTERACTIONS REVIEW

Strategic Considerations

An evolving body of evidence indicates that 5-HTP may be as effective as many conventional medications in the treatment of depression, anxiety, insomnia and other neuroendocrine conditions, generally with fewer adverse effects. "In functional dimensional parlance, treating a serotonin deficiency is tantamount to treating all symptoms figuring as behavioral expressions of the serotonin-dependent psychological dysfunctions," write Poldinger, Calanchini, and Schwarz.[1]

For many years, a broad assumption in the medical literature is that drug-nutriceutical interactions involving 5-HTP represent significant risks of frequent occurrence, severe character, and seemingly self-evident pharmacological characteristics. Such interactions between 5-HTP and pharmacological agents could theoretically be relatively common because 5-HTP and many medications with which it may interact are used to treat the same conditions and patient populations. Oral ingestion of 5-HTP in animals and humans seems to be able to cause symptoms (primarily diarrhea) associated with elevated serotonin. In an experimental model, 5-HTP plus a MAO inhibitor has been shown to produce a syndrome similar to serotonin syndrome.[2] However, there is a surprising dearth of scientific evidence from controlled clinical trials or documented case reports supporting or detailing this interaction of presumably high probability. A significant number of the "interactions" attributed to 5-HTP are actually extrapolations derived from case reports and trials involving drugs, particularly those that interfere with serotonin metabolism or regulation, and as such function through a fundamentally different mechanism of action than the nutritive supply enhancement model of therapeutics employing 5-HTP. The lack of documented interactions involving 5-HTP, in contrast to SSRIs or other pharmacological agents directly manipulating serotonin levels by impairing the regulatory processes of serotonin breakdown, might be interpreted to suggest that enhancement of 5-HTP levels through oral intake, in contrast to SSRIs or other pharmacological agents directly manipulating serotonin levels, may enable serotonin production when needed, without forcing up serotonin levels when feedback systems signal saturation. No evidence has emerged to indicate that serotonin syndrome or other adverse interaction phenomena can result from combining an SSRI agent with a protein-rich diet containing significant levels of L-tryptophan. Although a naturally occurring intermediate, 5-HTP is normally self-regulated in the body, with elevated levels rarely reported. Most likely, if 5-HTP production is upregulated for some reason (e.g., SNPs, diet, lifestyle), causing increased serotonin production, the body compensates by upregulating serotonin reuptake, keeping everything in balance.

Nevertheless, the combined use of 5-HTP and antidepressant drugs (including tricyclics, MAO inhibitors, and SSRIs, as well as other serotonin agonists) all present a significant probability of increased risk of adverse effects. In particular, widespread warnings have cautioned against the risk of *serotonin syndrome*, a dangerous but relatively rare condition caused by excess serotonin levels that could theoretically result from simultaneous 5-HTP intake in individuals whose serotonin regulation has been impeded by such medications. This potentially dangerous situation results from excess serotonin availability in the CNS at the 5-HT1A receptor; some interaction with dopamine and 5-HT2 receptors is also likely to be involved. Serotonin syndrome carries potentially serious clinical consequences and is characterized by the triad of altered mental status, autonomic dysfunction, and neuromuscular abnormalities. The serotonin syndrome is similar to the neuroleptic malignant syndrome and is usually differentiated by the setting of recent addition of a serotonergic agent. Specific symptoms can include agitation, anxiety, ataxia, confusion, delirium, diaphoresis, diarrhea, fever, hyperreflexia, myoclonus, incoordination, shivering, nausea, vomiting, and tremor. This phenomenon most often occurs with SSRIs, MAO inhibitors, opioids, and other serotonergic agents, when the serotonin system has been modulated by another serotonergic agent or compromised by illness. SSRIs, particularly fluoxetine, are most often involved in reported drug interactions inducing serotonin syndrome; because of their long elimination half-life (1 week for fluoxetine), the risk of interactions persists for several days or even weeks after SSRI withdrawal. Simultaneously elevating serotonin levels through introduction of precursors while inhibiting serotonin uptake and breakdown risks interaction scenarios. 5-HTP should never be combined with SSRIs or MAO inhibitors at any dose, except possibly in a carefully monitored inpatient clinical research setting.

Conversely, the concomitant use of 5-HTP and serotonin antagonists is likely to reduce the effectiveness of these agents. Nevertheless, the likelihood and frequency of such adverse events, as well as the respective levels of drug and nutrient intake at which this toxic effect might occur, remain unknown.

More broadly, clinicians treating individuals with depression, insomnia, and related conditions face the more profound and demanding task of helping these patients restore their lives to a healthy level of functionality, stability, and resilience. Comprehensive positive clinical outcomes cannot be achieved simply by medicating patients in adverse or stressful life circumstances. The fundamental therapeutic interventions in such circumstances require that health care providers work together to reempower these individuals by encouraging and supporting lifestyle changes involving exercise and healthy diet, changes in dysfunctional work or relationship behaviors and patterns, psychological counseling, and the challenges of personal growth. Despite repeated promises of pharmacologically induced emotional well-being based on "correction" of "brain chemistry," clinicians face the daily challenge of viewing antidepressants or other psychopharmacological interventions as "bridge therapies" within a broader therapeutic strategy, as "crutches" that give way to free walking and renewed vigor and equilibrium.

Nutraceuticals and herbal therapeutics that enhance neurotransmitter status can play important primary or adjunctive roles in such a broader strategic approach. Such a multimodality approach can often provide safe and effective intervention during certain phases of the therapeutic process to "round out" pharmacology or as alternatives to medications that primarily preempt or interfere with self-regulatory feedback systems.

NUTRIENT-DRUG INTERACTIONS

Dextroamphetamine and Related Stimulant Medications

Evidence: Amphetamine (amphetamine aspartate monohydrate, amphetamine sulfate); dextroamphetamine, dextroamphetamine saccharate, dextroamphetamine sulfate; D-amphetamine; Dexedrine; combination drug: mixed amphetamines: amphetamine and dextroamphetamine (Adderall; dexamphetamine).
Similar properties but evidence lacking for extrapolation: Methylphenidate (Metadate, Methylin, Ritalin, Ritalin-SR; Concerta).

Interaction Type and Significance

⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **3. Possible**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Serotonin may be involved in the modulation of psychotic symptoms in some forms of schizophrenia. Although frequently associated with aggressive behavior and other adverse effects, amphetamine use is generally not associated with symptoms of acute psychosis, except in individuals with schizophrenia. Administration of exogenous 5-HTP may mitigate adverse effects associated with therapeutic amphetamine use in schizophrenic patients through an unknown mechanism involving its role as a serotonin precursor.

Research

Amphetamines are well known to trigger acute schizophrenic breaks in susceptible individuals, which may require hospitalization. In an uncontrolled clinical trial, Irwin et al.[4] found that "preadministration with 5HTP significantly antagonized amphetamine-elicited elevations in thought disturbance, activation, and hallucinations" in schizophrenic patients.

No research appears to be available investigating potential synergy between 5-HTP and amphetamine agents in the treatment of broader patient populations or other conditions for which this drug class is employed (e.g., hyperactivity/ADHD).

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing D-amphetamine to patients diagnosed with schizophrenia or related psychiatric conditions are advised to consider the potential benefits of 5-HTP coadministration under close supervision. Such a situation is unusual and not likely to be encountered in most clinical settings.

Carbidopa and Related Antiparkinsonian Medications

Evidence: Carbidopa (Lodosyn).

Extrapolated, based on similar properties: Levodopa (L-dopa; Dopar, Larodopa); combination drugs: levodopa and benserazide (co-beneldopa; Madopar); levodopa and carbidopa (Atamet, Parcopa, Sinemet, Sinemet CR); levodopa, carbidopa, and entacapone (Stalevo).

Interaction Type and Significance

Supportive Interaction

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Adverse Effect

Probability: **3. Possible**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Abnormalities in tryptophan metabolism, particularly elevated kynurenine, have been associated with adverse dermatological reactions in some individuals administered both 5-HTP and carbidopa, which combines L-dopa with a peripheral decarboxylase inhibitor. It has been suggested that individuals with an abnormality in kynurenine hydrolase or another of the enzymes responsible for catabolizing kynurenine, an intermediate compound in tryptophan metabolism, might be susceptible to this reaction in the presence of carbidopa, when serotonin levels rise subsequent to 5-HTP intake.

Research

Some types of intention myoclonus are caused by a deficiency of brain 5HT (serotonin) and respond to serotonin precursor therapy (e.g., L-5-HTP). Clinical trials have found that the coadministration of carbidopa and 5-HTP may have a beneficial effect in the treatment of many individuals with intention myoclonus and related neuromuscular disorders. Growdon et al.[5] investigated the concomitant use of 5-HTP and carbidopa in eight individuals with posthypoxic intention myoclonus. They found a variable response depending on the individual and the form of myoclonus. These researchers concluded: "A patient's response to L-5-hydroxytryptophan therapy may be important in a diagnostic classification of myoclonic syndromes based on differences in indoleamine neurotransmitter function." Van Woert et al.[6] administered 5-HTP to 18 patients being treated for intention myoclonus caused by anoxia or other brain damage. Eleven derived more than 50% overall improvement during treatment with L-5-HTP and carbidopa. Cerebrospinal fluid 5-HIAA was 35% lower in patients with intention myoclonus than in controls. Combined therapy with L-5-HTP and carbidopa increased the concentration of serotonin metabolites in urine and CSF. These researchers postulated that "a deficiency of brain serotonin is causally related to intention myoclonus and that the therapeutic effect of L-5HTP and carbidopa may be due to the repletion of serotonin in regions of the brain where serotoninergic neurons have degenerated."[6] In subsequent research, Van Woert et al.[7] found that although fluoxetine alone provided no antimyoclonic effect when administered alone to four patients with intention myoclonus, a combination therapy using carbidopa, 5-HTP, and fluoxetine had a beneficial effect on serotonin in relation to intention myoclonus. Thus, "in two patients with intention myoclonus responsive to L-5HTP and carbidopa, fluoxetine reduced the required dose of L-5HTP to approximately one-third, with greater antimyoclonic activity, decreased side effects, and reduction in platelet 5HT and plasma 5-hydroxyindoleacetic acid and L-5HTP concentrations."[7]

A range of adverse effects have been noted in individuals being treated with such a regimen, including "persistent euphoria," early mania, rapid speech, restlessness, insomnia, aggressiveness, and diarrhea.

In a potentially relevant animal study, Bender and Smith[8] found that carbidopa inhibits kynurenine hydrolase, an enzyme involved in the biosynthesis of niacin.

In 1981, Magnussen et al.[9] measured the influence of L-aromatic amino acid decarboxylase inhibitors on single oral doses of L-5-HTP, as reflected in plasma concentrations of 5-HTP, 5-HT (serotonin), and 5-HIAA and the concentrations of serotonin in blood platelets. They observed that "carbidopa enhanced the rise in plasma concentrations of 5-HTP 5-15 fold and counteracted the increase in plasma 5-HIAA levels induced by 5-HTP alone. A single dose of the decarboxylase inhibitor

was equipotent to 14 days' pretreatment."[9] In a follow-up study the next year, this research team determined that neurological patients receiving steady-state treatment with 5-HTP demonstrated accumulation of 5-HT in blood platelets and 5-HIAA in plasma in all patients, despite concomitant administration of the L-aromatic amino acid decarboxylase inhibitors, carbidopa and benserazide. There was no correlation between the 5-HTP dose and the circulating concentrations of the amino acid or its metabolites. Preliminary comparison of the carbidopa versus benserazide suggest the 5-HTP/carbidopa combination appeared superior to 5-HTP/benserazide in terms of biochemical and therapeutic effects.[10]

Reports

Magnussen et al.[11] published a case report that offers some potentially valuable clues in understanding this interaction. They described a patient successfully treated for posthypoxic intention myoclonus by long-term coadministration of 900 mg 5-HTP daily and 150 mg carbidopa. By administering methysergide (12 mg/day), they were able to block the therapeutic effect, thus indicating a specific serotoninergic function of precursor loading with 5-HTP. Further, coadministration of tryptophan (8 g/day) exerted no beneficial effect on the myoclonus, thereby suggesting a reduced tryptophan hydroxylase activity.

Sternberg et al.[12] reported a scleroderma-like illness that developed in a patient treated with L-5-HTP and carbidopa for intention myoclonus. The patient had high plasma kynurenine levels that remained high when the L-5-HTP/carbidopa combination was discontinued and rose further when the drug was reintroduced, suggesting that the drug revealed an abnormality in an enzyme that catabolizes kynurenine. Cessation of 5-HTP, along with introduction of 100 mg vitamin B_6 daily (which enhances decarboxylase activity), was associated with gradual resolution of the scleroderma-like condition. Subsequently, these researchers found that plasma kynurenine was also elevated in 7 of 15 patients with idiopathic scleroderma, but not in eight patients with intention myoclonus treated with L-5-HTP and a decarboxylase inhibitor and in whom scleroderma did not develop, or in 10 patients with Parkinson's disease treated with L-dopa and carbidopa. They concluded that high plasma serotonin and a metabolic abnormality associated with elevated kynurenine were important in the pathogenesis of some scleroderma-like disorders.

Joly et al.[12a] also published a case report of hardening of the skin similar to scleroderma and pseudobullous morphea during therapy with 5-HTP and carbidopa. Subsequently, Auffranc et al.[13] reported a case of sclerodermiform and poikilodermal syndrome in a male patient receiving carbidopa and 5-HTP.

This adverse reaction is not widely associated with concomitant use of carbidopa and 5-HTP and appears to be related to particular pharmacogenomic factors shared by the affected individuals, but of unknown frequency in the general patient population. Reports of such scleroderma-like conditions in association with 5-HTP intake appear to be confined to the context of carbidopa therapy, presumably related to the decarboxylase inhibitor component of carbidopa slowing transformation of 5-HTP into serotonin in the peripheral circulation, with consequent elevation of kynurenine in susceptible individuals.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The combined use of carbidopa and 5-HTP appears to be a potentially beneficial therapeutic tool in the treatment of at least some individuals with intention myoclonus. However, physicians prescribing carbidopa should advise patients to avoid concomitant use of 5-HTP, except under coordinated care involving close supervision by a health care professional trained and experienced in nutritional therapeutics. Ideally, the emergence of pharmacogenomic testing will assist physicians by providing adequate information about the individual's ability to tolerate and benefit from the treatment combination.

Chlorimipramine and Related Tricyclic Antidepressants

Evidence: Chlorimipramine (clomipramine; Anafranil).
Extrapolated, based on similar properties: Amitriptyline (Elavil); combination drug: amitriptyline and perphenazine (Etrafon, Triavil, Triptazine); amoxapine (Asendin), desipramine (Norpramin, Pertofrane), doxepin (Adapin, Sinequan), imipramine (Janimine, Tofranil), nortriptyline (Aventyl, Pamelor), protriptyline (Vivactil), trimipramine (Surmontil).

Interaction Type and Significance

⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Chlorimipramine is a halogenated derivative of imipramine that is more potent as a serotonin (5-HT) reuptake inhibitor than the parent compound. Both chlorimipramine and exogenous 5-HTP can elevate serotonin and cortisol levels, and their concomitant use could potentially result in excessive levels as a result of an additive effect.

Research

In a pioneering clinical trial, van Praag et al.[14] found that the combination of 5-HTP and clomipramine proved more effective than clomipramine alone in the treatment of patients with "therapy-resistant" depression. Subsequently, in a 28-day double-blind clinical trial involving 26 hospitalized, depressed patients who were randomized into two groups, Nardini et al.[15] found that those subjects who received chlorimipramine (50 mg/day), combined with L-5-HTP (300 mg/day), demonstrated significantly better response, quantitatively and qualitatively, than did those who received chlorimipramine plus placebo, according to several standard depression scoring systems.

Meltzer et al.[16] noted that serum cortisol concentration was significantly greater in unmedicated depressed and manic patients than in normal controls after administration of 5-HTP, 200 mg orally. Further, increases in serum cortisol levels greater than 5 μg/dL were significantly more frequent in both unmedicated depressed and manic patients than in the normal controls. Subsequently, this same research team, determined that in subjects with major depression or with obsessive-compulsive disorder, most tricyclic antidepressants (TCAs) do not increase 5-HTP-mediated cortisol release, in contrast to fluoxetine, which does potentiate such a 5-HTP-mediated increase in plasma cortisol and prolactin secretion.[17] However, in a small clinical trial involving seven patients with major depression, Sargent et al.[18] observed that cortisol response to 5-HTP was significantly increased after 8 weeks' treatment with clomipramine, "suggesting that clomipramine,

like selective serotonin re-uptake inhibitors (SSRIs), enhances this 5-HT2 receptor mediated response."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The available literature indicates that the concomitant administration of clomipramine and 5-HTP may interact to elevate cortisol and serotonin levels. This effect could be therapeutically appropriate and efficacious or potentially risky, depending on the dosage levels, diagnosis, patient characteristics, and other factors. Any treatment program utilizing this combined action requires close supervision and regular monitoring and would be most safely and effectively undertaken within the context of the coordinated efforts of health care professionals trained and experienced in both conventional pharmacology and nutritional precursor therapeutics. Although the preliminary findings have been encouraging, further research with large, well-designed clinical trials is necessary to evaluate further the safety and efficacy of this integrative therapeutic option and to assist development of clinical guidelines.

Lithium Carbonate

Lithium carbonate (Camcolit, Carbolith, Duralith, Eskalith, Li-Liquid, Liskonum, Litarex, Lithane, Lithobid, Lithonate, Lithotabs, PMS-Lithium, Priadel).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability:
3. Possible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Both lithium and exogenous 5-HTP can elevate serotonin and cortisol levels as part of their therapeutic action. Concomitant use of these agents may induce excessively elevated serotonin levels and disrupt regulation of cortisol and other neuroendocrine substances.

Research

Lithium increases serotonin release and decreases metabolism. Despite lithium's proven efficacy as a long-term treatment for recurrent mood disorders (bipolar syndromes), individuals show a variable response, ranging from complete efficacy to no influence at all.[19,20] Serotonergic pathways appear to be important to the mechanisms of action of lithium. Much recent research has focused on identifying possible predictors of response through molecular genetic studies. Recent research has observed an association between genetic variation in tryptophan hydroxylase (TPH) and aggression and anger-related traits.[21] Clinical predictors apparently account for about half the variance in lithium response, and genetic factors probably play a substantial role in both risk factors and response factors in affective disorders.[22-24]

In 1999, Serretti et al.[25] published one of several papers examining the possible association between the TPH gene variants and prophylactic efficacy of lithium in mood disorders. In a review from 2002, Serretti[26] reported that the functional polymorphism in the upstream regulatory region of the serotonin transporter gene (5-HTTLPR) has been associated with long-term efficacy of lithium in two independent studies; marginal associations have been reported for TPH and inositol polyphosphate 1-phosphatase (INPP1). Even though no unequivocal susceptibility gene for lithium efficacy has been identified, individual pharmacogenomic variability significantly influences response patterns. Within that context, manipulation of tryptophan metabolism and serotonin synthesis appears to play an important role.

Meltzer et al.[27] investigated the hypothesis that lithium carbonate may enhance serotonin receptor sensitivity, whereas TCAs and second-generation antidepressants diminish 5-HT receptor sensitivity. They found that serum cortisol levels were significantly increased after administration of 5-HTP, 200 mg orally, to subjects with affective disorders. Further, 3 to 5 weeks of treatment with lithium carbonate or a MAO inhibitor augmented the mean 5-HTP-induced increase in serum cortisol concentration in manic or depressed patients, respectively.

Reports

Documented case reports confirming interactions between lithium and 5-HTP are lacking. Clinical observations suggest that 5-HTP (or tryptophan) can serve as a clinically effective adjunct to lithium therapy, particularly in the treatment of some individuals diagnosed as bipolar with mania or depression, for whom lithium, alone or in combination with neuroleptics or tricyclics, has demonstrated limited or no effect.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

5-Hydroxytryptophan administration potentially offers a valuable adjunct to lithium therapy in the management of some individuals with bipolar affective disorders. Besides enhanced therapeutic efficacy, such coordinated administration of lithium and 5-HTP provides an opportunity to reduce lithium doses and decrease attendant adverse effects, particularly in controlling acute mania and other severe conditions for which higher, more toxic doses of lithium are often required. Concomitant therapy may also achieve therapeutic efficacy with some individuals previously unresponsive to lithium alone or in combination with other psychoactive agents.

Controlled clinical trials involving coadministration of 5-HTP and lithium are lacking, so specific 5-HTP dosage recommendations cannot be made. However, in related research, some bipolar patients have demonstrated an increased sensitivity to L-tryptophan administration, with adverse reactions occurring at levels as low as 1 to 2 g daily. Based on functional parallels, low initial 5-HTP levels, slow and graduated increases in dosage, and regular monitoring are important to safe and effective concomitant medication.

5-Hydroxytryptophan, when administered to individuals undergoing lithium therapy, might increase some adverse effects associated with lithium therapy by potentiating the lithium effect; these include nausea, vomiting, dermatological eruptions, psoriasis, and alopecia. Gradual reduction of lithium in chronic cases, such as treatment of bipolar disorder, not only may be valuable for reduction of typical adverse effects associated with lithium, but also may be necessary because of an increase in lithium concentrations as a result of potentiation by 5-HTP. Monitoring of lithium concentrations for at least 2 weeks after introduction of 5-HTP or changes in lithium dosage is appropriate with such individuals. Individuals being treated for acute mania may be particularly sensitive to exacerbations because of alterations in effective concentrations of lithium. In such cases it may be appropriate to decrease the lithium dosage, especially with doses above 900 to 1200 mg per day. Implementation of such integrative strategies warrants active supervision and close monitoring by health care professionals trained and experienced in clinical nutrition and conventional pharmacology. Pharmacogenomic variability,

particularly involving TPH polymorphisms, appears to influence both individual susceptibility to bipolar disorder and related conditions and therapeutic response to lithium and 5-HTP.

Selective Serotonin Reuptake Inhibitor and Serotonin-Norepinephrine Reuptake Inhibitor (SSRI and SNRI) Antidepressants

Evidence: Fluoxetine (Prozac, Sarafem), fluvoxamine (Faurin, Luvox), paroxetine (Aropax, Deroxat, Paxil, Seroxat).
Extrapolated, based on similar properties: Citalopram (Celexa), duloxetine (Cymbalta), escitalopram (S-citalopram; Lexapro), sertraline (Zoloft), venlafaxine (Effexor).
See Venlafaxine in Theoretical, Speculative, and Preliminary Interactions Research.

2. Probable

Evidence Base:
○ Preliminary

Effect and Mechanism of Action

Selective serotonin reuptake inhibitor (SSRI) agents are designed to increase the functional level of serotonin in the brain by inhibiting its reuptake into the presynaptic neurons. SSRIs work acutely on synaptosomes in rat models but take several weeks to develop full antidepressant clinical effects in patients, which suggests the possibility of at least two different mechanisms. L-5-hydroxytryptophan (and L-tryptophan) are serotonin precursors that elevate serotonin stores.[28,29] Apparently eating a diet high in tryptophan does not significantly increase 5-HTP levels. However, the introduction of L-tryptophan, and especially 5-HTP, into the body through supplementation could increase available levels of serotonin and amplify the effects of any SSRI drugs.[30,31] This combination could potentially result in excessive levels of serotonin and produce an adverse reaction known as the "serotonin syndrome"; it could also alter the levels of other related hormones, such as cortisol, melatonin, and prolactin.[16,32] The serotonin syndrome is a potentially severe adverse drug interaction characterized by the triad of altered mental status, autonomic dysfunction, and neuromuscular abnormalities.

Research

Human research directly investigating 5-HTP intake is inconclusive in the context of conventional antidepressant therapy, despite widespread use of SSRIs and a presumption of consensus as to the high probability and serious risk of the interaction between SSRIs and 5-HTP. Several studies have favorably shown clinical efficacy and safety of 5-HTP compared with SSRIs and other conventional medications. In a 6-week, multicenter trial, for example, Poldinger et al.[1] reported 5-HTP to be as effective as fluvoxamine in treating severe depression. However, despite numerous data on adverse reactions, including serotonin syndrome, from patients taking SSRIs, limited direct evidence from controlled human clinical trials is available demonstrating the frequency, character, and severity of the presumed interaction between 5-HTP and SSRIs. Nevertheless, there have been reports of experienced clinicians safely and effectively using graduated doses of 5-HTP with reduced SSRI doses as a transitional device in weaning patients off SSRIs.

Meltzer et al.[17] found that fluoxetine potentiates the 5-HTP-mediated increase in plasma cortisol and prolactin secretion in subjects with major depression or with obsessive-compulsive disorder.

Using a rat model, Dreshfield-Ahmad et al.[33] reported elevation of extracellular serotonin levels by 5-HTP loading after administration of WAY 100635 (a selective 5-HT1A antagonist) and fluoxetine. These researchers concluded that their findings "suggest that combining blockade of 5-HT1A autoreceptors with 5-HT uptake inhibition results in a synergistic increase in synthesis and release of 5-HT when precursor is administered."

The complex issue of potential adverse effects on neurotransmitter and hormonal self-regulatory processes, including endogenous 5-HTP synthesis, resulting from long-term administration of SSRIs, has yet to be fully addressed. Using a rat model, Yamane et al.[33a] observed a reduction in serotonin synthesis after acute and chronic treatments with paroxetine. Conversely, Kim et al.[34] found that long-term treatment of rats with sertraline upregulated mRNA and protein levels of the serotonin-synthesizing enzyme TPH. They concluded that, in addition to the known short-term action as a serotonin uptake inhibitor, sertraline also exerts a long-term effect on the serotonin neurotransmission by enhancing serotonin synthesis. A parallel effect was observed with fluoxetine, but not with the non-SSRI chlorpromazine.

Research conducted by Serretti et al.[35,36] indicates that the antidepressant therapeutic response to SSRIs, specifically paroxetine and fluvoxamine, may be mediated by variations in the TPH and serotonin transporter genes. Further investigation into such pharmacogenomic factors may not only shed light on SSRI safety and efficacy, but also enhance understanding of individual susceptibility to depression and variable response to 5-HTP, as well as the probability of adverse interactions with exogenous 5-HTP intake.

Reports

A search of the available literature reveals a single case report involving combined use of L-tryptophan and paroxetine that resulted in headache, sweating, dizziness, agitation, restlessness, nausea, vomiting, and other symptoms, which could be representative of serotonin syndrome. However, although appearing pharmacologically probable, documented case reports are lacking to confirm interactions between SSRIs and 5-HTP. Even with a shortage of formal scientific data and published case reports, however, many health care professionals, particularly those practicing nutritional therapeutics using precursor substances, have treated patients who have self-administered 5-HTP while taking SSRIs and experienced adverse reactions of varying degrees of severity.

Clinical Implications and Adaptations

Physicians prescribing SSRI drugs are advised to warn patients to avoid concomitant 5-HTP (or L-tryptophan) unless they are under the direct care and coordinated supervision of the prescribing physician and a health care professional trained and experienced in nutritional psychopharmacology. Even though a potentially valuable synergy could develop from the careful combining of 5-HTP (or L-tryptophan) with SSRIs, such experimentation would be premature and should be considered potentially dangerous until well-designed, controlled clinical trials have been conducted. Because only a small amount of

ingested tryptophan is metabolized into serotonin, and because 5-HTP bypasses the rate-limiting step of serotonin synthesis (5-hydroxylation of tryptophan), the probability of untoward interactions between 5-HTP and SSRIs is higher than for tryptophan. At this time, tryptophan is available in the United States only by prescription through compounding pharmacies, despite tryptophan's therapeutic index being considerably higher than that of 5-HTP, which is widely available as an over-the-counter product.

Selegiline and Related Monoamine Oxidase (MAO) Inhibitors

Evidence: MAO-B inhibitors: Rasagiline (Azilect), selegiline (deprenyl, L-deprenil, L-deprenyl; Atapryl, Carbex, Eldepryl, Jumex, Movergan, Selpak).
Benserazide combination drug: Levodopa and benserazide (cobeneldopa; Madopar).
Similar properties but evidence lacking for extrapolation: MAO-A inhibitors: Isocarboxazid (Marplan), moclobemide (Aurorix, Manerix), phenelzine (Nardil), procarbazine (Matulane), tranylcypromine (Parnate).
See MAO-A Inhibitors in Theoretical, Speculative, and Preliminary Interactions Research.

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

The combined use of 5-HTP and a MAO-B inhibitor may result in a possible additive interaction that could be beneficial or could increase risk.

Research

Selegiline is an irreversible selective MAO-B inhibitor without "cheese effect," the severe hypertensive/adrenergic activation interaction that occurs between MAO-A inhibitors and foods containing tyramine (e.g., aged cheeses, some red wines). Selegiline is the primary type B MAO inhibitor in clinical use; it is most widely used with levodopa and carbidopa to treat symptoms of Parkinson's disease. No research has been conducted on the multivariable interaction of 5-HTP in the context of such polypharmacy. However, in a series of studies, Mendlewicz and Youdim[37,38] investigated coadministration of selegiline and 5-HTP in the treatment of individuals with affective illness. In an open-trial study, selegiline was given to patients with unipolar and bipolar depression receiving L-5-HTP and benserazide, a peripheral decarboxylase inhibitor that inhibits conversion of 5-HTP to serotonin outside the CNS. Of 14 patients, 10 showed a positive response to this combination, and a correlation was found between the degree of platelet MAO inhibition and clinical response. In a double-blind controlled study, 18 affectively ill patients were randomized to a group who received selegiline, L-5-HTP, and benserazide; 21 patients received L-5-HTP and benserazide only; and 19 were given placebo. The subjects treated with selegiline and L-5-HTP demonstrated a significantly greater clinical improvement than placebo patients; such beneficial effect was not observed in patients treated with 5-HTP/benserazide alone. These results are weakened by not having a selegiline-alone group, since an MAO inhibitor could certainly have antidepressant activity on its own.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing selegiline may want to discuss with patients the potentially valuable synergy from administering 5-HTP with their psychopharmacological intervention. Generally, such integrative therapeutics are best undertaken within the context of collaborative care involving health care professionals trained and experienced in both conventional pharmacology and nutritional psychopharmacology; close supervision and regular monitoring are warranted. Although the preliminary findings have been encouraging, further research with large, well-designed clinical trials is necessary to evaluate further the safety and efficacy of this integrative therapeutic option and to assist development of clinical guidelines.

Sibutramine and Related Serotonin Agonists

Evidence: Sibutramine (Meridia, Reductil).
Extrapolated, based on similar properties: Almotriptan (Axert), buspirone (Buspar), dihydroergotamine (DHE-45), ergotamine, eletriptan (Relpax), frovatriptan (Frova), naratriptan (Amerge), rizatriptan (Maxalt), sumatriptan (Imitrex), zolmitriptan (Zomig).
See also Sumatriptan, Zolmitriptan, and Related 5-Hydroxytryptamine Receptor Agonists (Triptans)

Interaction Type and Significance

✗✗✗ **Potentially Harmful or Serious Adverse Interaction—Avoid**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Serotonin agonists can enhance the serotonergic effect of other serotonin agonists, as well as serotonin precursors, thereby increasing the risk of augmenting serotonin activity to potentially toxic levels. In particular, the additive effect on serotonin activity resulting from concomitant use of 5-HTP and pharmaceutical serotonin agonists presents a significant risk of inducing serotonin syndrome.

The product information provided by the manufacturer of sibutramine states that because sibutramine "inhibits serotonin reuptake, it should not be administered with other serotonin agonists."[39]

Research

Using a rat model, Heal et al.[40] found that the combination of sibutramine and fluoxetine, at doses less than 10 mg/kg, had no effect on 5-HTP accumulation in either frontal cortex or hypothalamus, whereas sibutramine (10 mg/kg intraperitoneally) and fluoxetine (10 mg/kg intraperitoneally) produced slow, prolonged increases of extracellular 5-HT (serotonin) in the anterior hypothalamus. Overall, in investigating the action of several agents, these researchers interpreted their findings to show that "sibutramine powerfully enhances central 5-HT function via its secondary and primary amine metabolites; this effect, like that of fluoxetine, is almost certainly mediated through 5-HT uptake inhibition."

Nevertheless, there remains a lack of scientific evidence from human studies directly supporting or detailing this pharmacologically probable interaction. No clinical trials have

investigated the potential interaction between sibutramine and 5-HTP.

Reports

A search of the literature reveals no documented case reports confirming interactions between sibutramine and 5-HTP. Thus, scientific evidence is currently lacking as to the frequency, character, or severity of this potential interaction.

Clinical Implications and Adaptations

The concomitant use of 5-HTP and agents that enhance serotonin activity is contraindicated and, if determined to be necessary in a particular case, should only be undertaken from within the context of close clinical supervision and regular monitoring. Adverse effects of a dangerous additive or synergistic interaction are likely to be characterized by rapid onset of toxicity symptoms characteristic of serotonin syndrome.

Sumatriptan, Zolmitriptan, and Related 5-Hydroxytryptamine Receptor Agonists (Triptans)

Almotriptan (Axert), eletriptan (Relpax), frovatriptan (Frova), naratriptan (Amerge), rizatriptan (Maxalt), sumatriptan (Imitrex), zolmitriptan (Zomig).

See also Sibutramine and Related Serotonin Agonists.

Interaction Type and Significance

✗✗✗ **Potentially Harmful or Serious Adverse Interaction—Avoid**

Probability:
2. Probable

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Triptans are 5-hydroxytryptamine (5-HT1B/1D) agonists; they also activate the 5-HT1B receptors on coronary arteries, which is the basis for the potentially dangerous adverse effect of coronary spasm with use of triptans. Their antimigraine activity is attributed to stimulation of serotonin receptors in the brain. Serotonin agonists can enhance the serotonergic effect of other serotonin agonists, as well as serotonin precursors, thereby increasing the risk of augmenting serotonin activity to toxic levels. The introduction of exogenous 5-HTP into the context of pharmaceutical serotonin agonists carries a significant risk of an additive effect, resulting in excessive elevation of functional serotonin levels and potentially inducing serotonin syndrome.

Research

As a class, triptans are well known for a high degree of variability in their therapeutic action, numerous adverse effects, and frequent interactions with other agents. In a paper reviewing the safety and clinical use of triptans, Tepper[40a] wrote: "Some triptans have the potential for significant drug-drug interactions (sumatriptan, rizatriptan, and zomitriptan and monoamine oxidase inhibitors; rizatriptan and propranolol; zolmitriptan and cimetidine; and eletriptan and CYP3A4 metabolized medications and p-glycoprotein pump inhibitors)." In an important review paper, Saper[40b] simply declared: "What matters is not the differences between triptans, but the differences between patients."

Nevertheless, despite the apparently formulaic potential for clinically significant interactions, there remains a lack of scientific evidence from human studies directly supporting or detailing this pharmacologically probable interaction. No clinical trials have investigated the potential interaction between triptan agents and 5-HTP.

Reports

A search of the literature reveals no documented case reports confirming interactions between triptan selective serotonin receptor agonists and 5-HTP. Thus, scientific evidence is lacking as to the frequency, character, or severity of this potential interaction.

Clinical Implications and Adaptations

Triptans are a primary therapy for migraines within conventional practice, and several studies have demonstrated efficacy of 5-HTP in the treatment of migraines.[41-43] Consequently, there is a need for explicit communication and coordination to prevent the combined use of these agents, particularly with unsupervised patient self-care. Even though a potentially valuable synergy could develop from the careful combining of 5-HTP (or L-tryptophan) with triptans, such experimentation would be premature and should be considered potentially dangerous until well-designed, controlled clinical trials have been conducted.

The concomitant use of 5-HTP and agents such as triptan selective serotonin receptor agonists that enhance serotonin activity is contraindicated and, if determined to be therapeutically necessary in a particular case, should only be undertaken within the context of close clinical supervision and regular monitoring. Adverse effects of a dangerous additive interaction are likely to be characterized by rapid onset of toxicity symptoms.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

"Atypical Antipsychotics"

Aripiprazole (Abilify, Abilitat), clozapine (Clozaril), olanzapine (Symbyax, Zyprexa), quetiapine (Seroquel), risperidone (Risperdal), ziprasidone (Geodon).

Atypical antipsychotics are often used "off label" for many conditions other than schizophrenia. They are well known to interact with serotonin as well as many other receptors. It is generally advisable to avoid concomitant use of these agents and 5-HTP.

Monoamine Oxidase (MAO-A) Inhibitors

Isocarboxazid (Marplan), moclobemide (Aurorix, Manerix), phenelzine (Nardil), procarbazine (Matulane), tranylcypromine (Parnate).

Despite a lack of data from clinical trials or well-documented case reports, the general consensus is that the combined use of 5-HTP and MAO-A inhibitors carries significant potential adverse reactions similar to serotonin syndrome. Adverse effects of a dangerous additive or synergistic interaction of this nature are likely to be characterized by rapid onset of toxicity symptoms.

Tramadol

Tramadol (Tramake, Ultram, Zamadol, Zydol).

Tramadol is a synthetic opiate receptor agonist/antagonist analgesic that also blocks serotonin reuptake in the brain. L-5-Hydroxytryptophan (and L-tryptophan) are serotonin precursors that elevate serotonin stores. Simultaneous use could amplify the effects of tramadol, excessively elevate functional levels of serotonin, and thereby possibly increase the risk of tramadol-induced adverse effects, including serotonin syndrome.

No clinical trials have investigated the potential interaction between tramadol and 5-HTP. Consequently, although

pharmacologically plausible, research-based data are lacking as to the frequency, character, or severity of this potential interaction.

The literature contains numerous case reports of adverse interactions, including serotonin syndrome, in individuals taking tramadol and other antipsychotic and antidepressant medications, particularly fluoxetine and paroxetine.[44-51] However, documented case reports are currently lacking to confirm interactions between tramadol and 5-HTP.

Physicians prescribing tramadol should warn patients to avoid the use of concomitant 5-HTP unless they are under the direct care and coordinated supervision of the prescribing physician and a health care professional trained and experienced in nutritional psychopharmacology. Even though a potentially valuable synergy could develop from the careful combining of 5-HTP (or L-tryptophan) with tramadol, such experimentation would be premature and should be considered as carrying significant risk of adverse effects until well-designed, controlled clinical trials have been conducted.

Trazodone

Trazadone (Desyrel).

Trazodone is a weak serotonin reuptake inhibitor drug. Adverse reactions characterized as similar to serotonin syndrome have been reported in patients taking trazodone in conjunction with medications that increase CNS serotonin levels, notably SSRI drugs.[52-55] At this time, however, there is a lack of documented case reports confirming direct interactions between trazodone and 5-HTP.

The use of 5-HTP to wean patients off trazodone has been effectively employed within the context of collaborative and supervised integrative care. Nevertheless, concomitant use of trazodone and serotonin precursors such as 5-HTP is generally contraindicated, except perhaps under the direct care and coordinated supervision of health care professionals trained and experienced in both conventional pharmacology and nutritional psychopharmacology. This potentially valuable synergy warrants further investigation through well-designed, controlled clinical trials.

Venlafaxine

Venlafaxine (Effexor).

Similar Properties: Duloxetine (Cymbalta).

Venlafaxine is a phenethylamine bicyclic derivative, chemically unrelated to tricyclic, tetracyclic, or other available antidepressant agents. It is known to be a potent serotonin reuptake inhibitor (as well as a potent dopaminergic agonist) and has been associated with several cases of serotonin syndrome. As such, there is high probability of this medication interacting with exogenous 5-HTP and resulting in adverse effects because of excessively elevated functional levels of serotonin.

Nevertheless, scientific evidence is lacking to support or detail this pharmacologically probable interaction. No clinical trials have investigated the potential interaction between venlafaxine and 5-HTP. Likewise, a search of the literature reveals no documented case reports confirming direct interactions between venlafaxine and 5-HTP. Thus, scientific evidence is currently lacking as to the frequency, character, or severity of this potential interaction.

Physicians prescribing venlafaxine should warn patients to avoid the use of concomitant 5-HTP unless they are under the direct care and coordinated supervision of the prescribing physician and a health care professional trained and experienced in nutritional psychopharmacology. Even though a potentially valuable synergy could develop from the careful dose titration of 5-HTP with venlafaxine, such experimentation would be premature and should be considered potentially dangerous until well-designed, controlled clinical trials have been conducted.

Zolpidem

Zolpidem (Ambien, Stilnoct).

Similar Properties: Eszopiclone (Lunesta).

Zolpidem is a hypnotic drug used for short-term treatment of insomnia. Reports describing nine cases of suspected adverse interaction between zolpidem and serotonin reuptake inhibitor antidepressants, including hallucinations of several hours' duration, have been published.[56] No clinical trials have investigated the potential interaction between zolpidem and 5-HTP. Likewise, a search of the literature reveals no documented case reports confirming direct interactions between zolpidem and 5-HTP.

Physicians prescribing zolpidem should warn patients to avoid the use of concomitant 5-HTP unless they are under the direct care and coordinated supervision of the prescribing physician and a health care professional trained and experienced in nutritional psychopharmacology. Even though a potentially valuable synergy could develop from the careful combining of 5-HTP with zolpidem, such experimentation would be premature and should be considered potentially dangerous until well-designed, controlled clinical trials have been conducted.

NUTRIENT-NUTRIENT INTERACTIONS

Melatonin

The concomitant use of 5-HTP and melatonin may result in additive effects. The two agents are often used together clinically based on such observed activity. This potentially valuable synergy warrants further investigation through well-designed, controlled clinical trials.

S-Adenosylmethionine (SAMe)

The concomitant use of 5-HTP and SAMe may result in additive effects because SAMe-mediated methylation appears to enhance CNS neurotransmitter synthesis. The two agents are often used together clinically based on such observed activity. This potentially valuable synergy warrants further investigation through well-designed, controlled clinical trials. Supervision and monitoring are warranted with coadministration pending conclusive research findings.

Tryptophan

The concomitant use of 5-HTP and L-tryptophan will probably result in some additive effects. Dietary sources of tryptophan have not been found to raise levels of 5-HTP. This potentially valuable synergy warrants further investigation through well-designed, controlled clinical trials.

Vitamin B_6 (Pyridoxine)

Vitamin B_6 activates the decarboxylase enzyme that converts 5-HTP to serotonin in the bloodstream. The two agents are often used together clinically based on such observed activity. However, peripheral decarboxylation (potentially enhanced by B_6) may increase peripheral (outside the CNS) conversion of 5-HTP to serotonin, which then binds to gastrointestinal receptors, causing unpleasant side effects, such as nausea and diarrhea. In the analogous case of L-dopa (dihydroxyphenylalanine),

a peripheral decarboxylase inhibitor is coadministered to prevent peripheral conversion of L-dopa to dopamine, so that more L-dopa is converted to dopamine within the CNS to drive the remaining dopaminergic neurons in parkinsonian brains. This explains the trade name "Sinemet" for carbidopa/L-dopa, literally, "without metabolizing," meaning in the extra-CNS compartment. For this reason, vitamin B_6 is contraindicated with carbipoda or benserazide and L-dopa combinations. Thus, an argument could be made that vitamin B_6 given with 5-HTP might be counterproductive. This potentially important interaction warrants further investigation through well-designed, controlled clinical trials. Supervision and monitoring are warranted with coadministration pending conclusive research findings.

HERB-NUTRIENT INTERACTION

St. John's Wort

St. John's Wort *(Hypericum perforatum)*.

The concomitant use of 5-HTP and *Hypericum perforatum* may result in additive effects, particularly in the treatment of mild to moderate depression. One of the multiple St. John's wort mechanisms of action appears to resemble SSRI-like activity. The two agents are often used together clinically based on such observed activity. A typical combination would provide 50 to 100 mg of 5-HTP and 150 to 300 mg of St. John's wort extract (standardized for 0.3% hypericin), three times daily. This potentially valuable synergy warrants further investigation through well-designed, controlled clinical trials.

The 60 citations for this monograph, as well as additional reference literature, are located under 5-Hydroxytryptophan on the CD at the back of the book.

Alpha-Lipoic Acid

Nutrient Name: Alpha-lipoic acid.
Synonyms: Alpha lipoic acid, ALA, acetate replacing factor, bileton, lipoic acid, lipoicin, thioctacid, thioctan, thioctic acid.
Related Substance: Alpha-dihydrolipoic acid (DHLA); dihydrolipate.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Cisplatin, oxaliplatin Platinum chemotherapy ☼/⊕⊕	Alpha-lipoic acid (ALA) may protect neural and otic tissue from oxidative damage induced by platinum-based chemotherapy. Strong trend of evidence indicating clinically significant supportive interaction. Clinical protocols emerging.	Coadminister; timing and sequence may vary with agent. Supervise and monitor.
Gentamicin, amikacin Aminoglycoside antibiotics ☼/⊕⊕	ALA may protect kidney, liver, and inner ear tissues by providing antioxidant protection against aminoglycoside-induced free-radical generation and lipid peroxidation. Preliminary direct and consistent related evidence suggests that supportive interaction reasonably predictable as clinically significant.	Consider coadministration, especially with extended aminoglycoside use.
Haloperidol ☼/⊕⊕	ALA may provide antioxidant protection against hydrogen peroxide generation and oxidative stress due to excess dopamine turnover associated with haloperidol. Preliminary direct and consistent related evidence suggests that supportive interaction reasonably predictable as clinically significant.	Consider coadministration, especially with extended haloperidol use.
Irbesartan Angiotensin II receptor antagonists ⊕⊕	Concurrent use of ALA and irbesartan can produce an additive or synergistic response, producing improvements in endothelial function and reductions in markers of inflammation in patients with metabolic syndrome. Strategic interaction consistent with known activity of these agents on angiotensin II activity, proinflammatory processes, and oxidative stress.	Coadministration could support clinical outcomes in patients with metabolic syndrome, hypertension, or dysglycemic patterns. Monitor blood pressure, insulin response, and inflammatory markers.
Oral hypoglycemic agents Insulin ✗/⊕✗/⊕⊕	Concurrent use of ALA and oral hypoglycemic agents could theoretically produce an additive or synergistic response resulting in hypoglycemia due to ALA's supportive effect on glucose and insulin metabolism. Strategic interaction consistent with known activity of both agents, but consistent direct evidence of pharmacological interaction lacking.	Coadministration could support clinical outcomes in dysglycemic patients. Monitor blood glucose levels.

NUTRIENT DESCRIPTION

Chemistry and Forms

1,2-Dithiolane-3-pentanoic acid; 1,2-dithiolane-3-valeric acid; 6,8-thioctic acid; alpha-lipoic acid; 5-(1,2-dithiolan-3-yl) valeric acid.

Physiology and Function

Known by many names, alpha-lipoic acid (ALA) is a naturally occurring, fat-soluble and water-soluble, vitamin-like antioxidant and enzyme cofactor. It is involved in antioxidant protection and cell damage prevention, energy production and blood sugar regulation, growth stimulation and regulation of gene transcription, detoxification, and toxic metal chelation. Although the enzyme pathway for its de novo synthesis has not been fully elucidated, cysteine appears to be the source of sulfur, and octanoate serves as the intermediate precursor for the 8-carbon fatty acid. ALA is readily converted into dihydrolipoic acid (DHLA), its reduced form, in many tissues of the body. ALA is not required in the diet and therefore is not considered a true vitamin, because it can be synthesized by humans, as well as plants and other animals.

Lipoic acid was first isolated in 1951 by Reed and coworkers, in the course of research on "potato growth factor" in lactic acid bacteria, as a catalytic agent associated with pyruvate dehydrogenase; it serves as a coenzyme in the Krebs cycle and functions in the same manner as many B-complex vitamins. *Lipoamide*, the protein-bound form of the naturally occurring isomer *R*-alpha-lipoic acid, where it is covalently attached through the carboxylic acid to lysine residues, is a required cofactor for several multienzyme complexes that catalyze energy metabolism reactions within mitochondria. The pyruvate dehydrogenase complex and the alpha-ketoglutarate dehydrogenase complex both catalyze reactions within the citric acid cycle. The alpha-ketoacid dehydrogenase complex catalyzes the metabolism of leucine, isoleucine, and valine, the three branched-chain amino acids. ALA also increases glucose transport and improves heart rate variability. Biliary excretion, electrochemically inactive degradation products, and complete utilization of ALA appear to be the primary substrate in the endogenous metabolism. Urinary excretion of ALA and its main metabolites does not play a significant role in ALA elimination.

Alpha-lipoic acid is a carboxy acid with two sulfur atoms that can be oxidized or reduced and thus, along with glutathione, is one of the thiol antioxidants. Lester Packer, PhD, of the University of California–Berkeley, and others demonstrated the potent antioxidant activity of ALA and described it as the "universal," "ideal," and "metabolic" antioxidant because of its unique ability to neutralize free radicals in both lipophilic and hydrophilic environments and operate effectively throughout all tissues, including the brain. The low molecular weight and lipophilicity of ALA also enables it to cross the blood-brain barrier and may contribute to its protective effects on brain and neural tissue. ALA directly supports the liver in its detoxifying functions and plays an important role

enhancing the activity of the body's systemic "antioxidant network." ALA and dihydrolipoic acid (DHLA), also known as dihydrolipoate, both act as powerful antioxidants, protecting against oxidative damage by interacting with potentially damaging reactive oxygen and nitrogen species. In particular, the two forms work together to quench peroxynitrite radicals, an especially destructive class of free radicals consisting of both oxygen and nitrogen, which are known to play a role in the pathophysiology of chronic inflammation, atherosclerosis, lung disease, and neurological disorders. DHLA also enhances the uptake of cysteine by cells to enable increased glutathione synthesis and support intracellular glutathione levels. Furthermore, ALA and DHLA facilitate the synergistic relationship among antioxidants by regenerating ascorbic acid from dehydroascorbic acid, indirectly regenerating vitamin E, and reducing the oxidized forms of vitamin C, glutathione, and coenzyme Q10 to extend their metabolic life spans. Both ALA and DHLA may also chelate free metal ions, such as iron, copper, and arsenic, and prevent them from generating highly reactive free radicals that induce oxidative damage. Lastly, ALA (and DHLA) may play a role in repair of oxidative damage.

Alpha-lipoic acid also regulates signal transduction of nuclear factor kappa B (NF-κB), a transcription factor protein that binds to DNA and affects the rate of transcription of certain genes, with NF-κB-binding sites. By inhibiting the activation of NF-κB, ALA may influence a wide range of pathological processes, including inflammation, atherosclerosis, diabetes, hypertension, glaucoma, cancer, and acquired immunodeficiency syndrome (AIDS).

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Alpha-lipoic acid has been used clinically to protect against oxidative stress, to enhance mitochondrial function, to support healthy liver and neurological function, and to reduce the cellular effects of aging. In a clinical trial investigating in vivo antioxidant activity of ALA in healthy humans, Marangon et al.[1] found that a 4-month course of 600 mg/day significantly decreased several biomarkers of oxidative stress compared to baseline. Pharmacokinetic studies of oral ALA suggest that it might be most effectively administered in divided doses throughout the day, rather than in a single daily dose, because it is rapidly absorbed, rapidly metabolized, and rapidly cleared from plasma and tissues.

Historical/Ethnomedicine Precedent

Alpha-lipoic acid has not been used historically as an isolated nutrient.

Possible Uses

Age-related macular degeneration, Alzheimer's disease (dementia), *Amanita* poisoning, antioxidant support, cancer, cataracts, cellular oxidative damage, diabetic polyneuropathy, glaucoma, hepatitis C, human immunodeficiency virus and acquired immunodeficiency syndrome (HIV/AIDS) support, insulin resistance, ischemia-reperfusion injury, metal chelation, neuralgias, surgical recovery, type 2 diabetes mellitus.

Deficiency Symptoms

De novo synthesis generally prevents ALA deficiency, which has not been described per se. Nevertheless, the destruction of its cofactor form may play an important role in numerous pathophysiological processes. For example, individuals with primary biliary cirrhosis may have circulating antibodies to lipoamide-containing enzyme subunits.[2] Likewise, arsenic can render ALA inactive in arsenic toxicity by forming a complex with ALA in dehydrogenase enzymes.[3]

Dietary Sources

Limited quantitative information is available regarding ALA content in various food sources, and research into the relationship of dietary sources to circulating free ALA is in preliminary stages. Most dietary ALA is derived from lipoamide-containing enzymes and delivered as lipoyllysine (i.e., bound to lysine), which digestive enzymes may not effectively cleave.[3]

Foods that contain mitochondria, especially red meat, are believed to provide the highest levels of alpha-lipoic acid. Other animal sources include heart, liver, kidney, and skeletal muscle (i.e., red meat). Broccoli, spinach, tomatoes, and potatoes are rich plant sources of lipoyllysine, with yeast, peas, brussels sprouts, and rice bran having lower amounts.[4]

Nutrient Preparations Available

The *R*-isomer of alpha-lipoic acid is the form synthesized naturally and is the only form that functions as a cofactor for mitochondrial enzymes; it is currently commercially available. Previously, ALA was exclusively available as a 50/50 racemic mixture of the two optical isomers, *R*-alpha-lipoic acid and *S*-alpha-lipoic acid, as rendered by conventional chemical synthesis. *R*-ALA has greater bioavailability than *S*-ALA when administered orally and is reduced within the mitochondria to DHLA 28 times more rapidly, hypothetically providing significantly greater antioxidant activity.[5]

Dosage Forms Available

Capsule.

Dosage Range

Adult

Dietary: Alpha-lipoic acid is created in the human body and thus is not an essential nutrient. Consequently, humans are usually not deficient in ALA.
Supplemental/Maintenance: 20 to 50 mg/day.
Pharmacological/Therapeutic: 50 to 400 mg/day.

The amount of ALA used in research has ranged from 150 to 600 mg per day, with 600 mg/day being used to treat diabetic neuropathies and 150 mg/day for glaucoma.
Toxic: No upper limit (UL) dose has been established.

SAFETY PROFILE

Overview

Alpha-lipoic acid has been well tolerated and is considered to be extremely safe in the dosages typically used in clinical settings (e.g., 600 mg/day). When administered under medical supervision to patients with diabetic neuropathy, oral doses as high as 1200 mg/day (600 mg twice daily) for 2 years and 1800 mg/day (600 mg three times daily) for 3 weeks produced no adverse effects. No cases of toxicity from ALA overdose in humans have been published or otherwise reported. Nevertheless, no long-term studies have yet systematically evaluated the safety of ALA in healthy adults.

Nutrient Adverse Effects

General Adverse Effects
Skin rash (occasional).

Pregnancy and Nursing
There are no reports of adverse reactions. However, because no studies have confirmed the safety or documented any dangers of using ALA during pregnancy, nutraceutical intake should be avoided by pregnant or lactating women until safety has been demonstrated.

Contraindications

Use of ALA and other antioxidants is controversial during radiation therapy and some forms of chemotherapy.

Precautions and Warnings

Theoretically, as discussed later, orally administered ALA might enhance the effects of insulin and oral hypoglycemic agents and induce hypoglycemia.

INTERACTIONS REVIEW

Strategic Considerations

Although research into the biological activity of alpha-lipoic acid has been underway for more than 40 years, scientific knowledge of its potential role in clinical medicine has only recently begun emerging in a comprehensive and cohesive picture. The significant antioxidant activity of ALA and alpha-dihydrolipoic acid (DHLA), as well as other modes of biological activity, presents numerous apparent, and many as-yet undiscovered, opportunities for concomitant use with conventional medications, in both the prevention and the reduction of drug adverse effects, as well as through collaborative implementation of integrative strategies and by invoking beneficial or supportive interactions within the context of professional management. Even though *R*-ALA is the naturally occurring form and has superior pharmacokinetic characteristics, almost all human clinical trials of ALA administration have been performed using racemic ALA.[6] Furthermore, continued research into ALA's relative role in antioxidant networks will undoubtedly reveal deeper implications for its physiological functions and clinical applications. Thus, more refined research design is warranted to enable advancement of clinical knowledge concerning the therapeutic use and efficacy of alpha-lipoic acid.

NUTRIENT-DRUG INTERACTIONS

Cisplatin and Related Platinum Chemotherapy Compounds

Evidence: Cisplatin (*cis*-diaminedichloroplatinum, CDDP; Platinol, Platinol-AQ).
Extrapolated, based on similar properties: Carboplatin (Paraplatin), oxaliplatin (Eloxatin).

Interaction Type and Significance
☼ **Prevention or Reduction of Drug Adverse Effect**
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action
The antioxidant activity of alpha-lipoic acid appears to protect neural and otic tissue from oxidative damage associated with cisplatin, oxaliplatin and related agents, particularly with regard to renal systems and lipid peroxidation.

Research

Ototoxicity is a widely recognized and often severe adverse effect associated with cisplatin therapy. In an experimental model using rats, Rybak, Somani, et al.[7] investigated the effects of ALA (at variable doses of 25-100 mg/kg) on cisplatin-induced ototoxicity, compared with controls receiving no cisplatin. In their first published study, they concluded that ALA conferred significant, dose-dependent protection against cisplatin ototoxicity at all dose levels, and that such beneficial effect was further demonstrated by improved metabolic markers for glutathione and oxidative stress. The next year (2000) they came to similar conclusions. In particular, they observed that after cisplatin administration, renal superoxide dismutase, catalase, glutathione peroxidase (GSH peroxidase), and glutathione reductase activities decreased significantly, and malondialdehyde content doubled, and that these changes were reversed by increasing doses of ALA. They also found that renal platinum concentration increased after cisplatin administration, which they attributed as possibly decreased by chelation with lipoic acid. These findings suggest that the "graded doses of alpha-lipoic acid effectively prevented a decrease in renal antioxidant defense system and prevented an increase in lipid peroxidation, platinum content and plasma creatinine concentrations in a dose-dependent manner."[8] In a preliminary clinical trial, Gedlicka et al.[9] reported that ALA coadministration, including infusions, produced a significant pattern of amelioration of docetaxel/cisplatin-induced polyneuropathy.

Peripheral sensory neuropathy, with both acute and cumulative symptoms, is one of the most common and clinically significant adverse effects associated with oxaliplatin and other platinum-based chemotherapeutic regimens. Approximately 85% to 95% of patients receiving oxaliplatin experience acute transient neuropathy, particularly distal and peroral dysesthesia. Cumulative neuropathies, manifesting the dose-limiting toxicity of oxaliplatin, develop progressively in 10% to 18% of patients who have been administered a cumulative dose of 800 mg/m^2.[10] In a small, human clinical trial, Gedlicka et al.[11] found that ALA, 600 mg intravenously once weekly for 3 to 5 weeks, followed by 600 mg orally three times daily, effectively counteracted cumulative oxaliplatin-related peripheral sensory neuropathy (PNP). Eight of 15 (53%) patients reported that ALA effectively reduced the severity of this dose-limiting oxaliplatin-related adverse effect. These authors recommended further larger-scale, placebo-controlled research.

Nutritional Therapeutics, Clinical Concerns, and Adaptations
The emerging body of research strongly suggests that coadministration of ALA with platinum-based chemotherapeutic agents such as cisplatin and oxaliplatin may serve as a safe and effective adjuvant therapy capable of decreasing the neurological and ototoxic effects resulting from drug-induced oxidative damage. Because ALA can chelate heavy metals, careful randomized trials with both arms carefully stratified to have equivalent prognostic factors will be necessary to be certain that concomitant ALA therapy with platinum-based therapies (as well as other neurotoxic chemotherapies, e.g., taxanes, vinca alkaloids) does not compromise efficacy of the chemotherapy.

Patients offered such therapy should be informed of the preliminary work done, and that although ALA likely can provide neuroprotection from neurotoxic chemotherapy, we cannot be certain at this time that it would definitely not compromise chemotherapy efficacy. This is much less of an issue when palliative chemotherapy is involved, but when chemotherapy is given with curative intent, such as for germ cell tumors, careful monitoring of clinical response and full disclosure to the patient and family regarding current evidence are essential. Such integrative approaches to oncology care require a high level of collaboration among health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics, usually obtained only in multidisciplinary oncology clinics.

Gentamicin, Amikacin, and Related Aminoglycoside Antibiotics

Evidence: Amikacin (Amikin), gentamicin (G-mycin, Garamycin, Jenamicin).
Extrapolated, based on similar properties: Kanamycin (Kantrex), neomycin (Mycifradin, Myciguent, Neo-Fradin, NeoTab, Nivemycin), netilmicin (Netromycin), paromomycin (monomycin; Humatin), streptomycin, tobramycin (AKTob, Nebcin, TOBI, TOBI Solution, TobraDex, Tobrex).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **3. Possible**
Evidence Base: **○ Preliminary**

Effect and Mechanism of Action

Free-radical generation and lipid peroxidation associated with gentamicin and other aminoglycosides play an important role in drug-induced damage to the liver, kidneys, and inner ear.[12] Alpha-lipoic acid can act as a powerful antioxidant and free-radical scavenger, especially against nephrotoxicity and ototoxicity.

Research

Sandhya and Varalakshmi[13] found that the intraperitoneal administration of gentamicin to rats is associated with an increased production of malondialdehyde (MDA), an end product of lipid peroxidation in the kidney, as well as decreased renal levels of glutathione (GSH) and decreased activity of superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GPx), three antioxidant systems in the kidney. In contrast, they observed that the coadministration of gentamicin and DL-alpha-lipoic acid decreased lipid peroxidation as well as increased GSH level and activity of SOD, CAT, and GPx. These authors concluded that "administration of DL-alpha-lipoic acid prevents lipid peroxidation, which may, at least partly, play an important role in the injury cascade of gentamicin-induced nephrotoxicity." Subsequently, Conlon et al.[14] conducted studies using guinea pigs to investigate the ability of ALA (100 mg/kg/day) to attenuate the cochlear damage induced by amikacin, 450 mg/kg/day intramuscularly. Their results showed that animals receiving ALA in combination with amikacin demonstrated a significant decrease in the severity of changes in cochlear function compared with animals receiving amikacin alone.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Aminoglycoside antibiotics are indicated in the treatment of serious systemic infections for which less toxic antibacterials are ineffective or contraindicated, but they are strongly associated with numerous toxicities, particularly involving the kidneys and nerves of the inner ear. Because the preliminary research on this topic has involved animals and not human patients, no conclusive recommendations can be offered. However, a diverse set of clinical studies has demonstrated ALA's role as a potent antioxidant and its ability to enhance protective systems in the kidneys, liver, and inner ear in a variety of situations. Therefore, although coadministration of ALA might be advisable for individuals being treated with aminoglycosides, the available research literature provides no specific indications as to the appropriate dosage for such concomitant use. Physicians prescribing gentamicin and related aminoglycosides are advised to work in close collaboration with health care professionals trained and experienced in nutritional therapeutics and closely monitor patients choosing to use ALA during and after aminoglycoside therapy.

Haloperidol

Haloperidol (Haldol).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **3. Possible**
Evidence Base: **○ Preliminary**

Effect and Mechanism of Action

Haloperidol, a widely used neuroleptic, acts through blockade of dopamine receptors, leading to increased turnover of dopamine. Excessive production of hydrogen peroxide and thus generation of oxidative stress are predictable outcomes from such increased turnover of dopamine. The antioxidant activity of alpha-lipoic acid, as well as that of glutathione, may protect against and reverse free-radical damage.

Research

Using a rat model, Shivakumar and Ravindranath[15] demonstrated that chronic administration of haloperidol induced significant oxidative stress and thiol modification in brain tissue, particularly after the first month. However, after 6 months of haloperidol administration, the glutathione-protein thiol homeostasis was largely restored, and the concentration of lipid peroxidation products decreased. Subsequently, Balijepalli et al.[16] examined the effects of a variety of classic and atypical neuroleptic drugs and found that haloperidol was the most potent inhibitor of mitochondrial NADH ubiquinone oxidoreductase (complex I) activity. They found that in vitro treatment of mouse brain slices with haloperidol resulted in a loss of glutathione, and that pretreatment of slices with glutathione and ALA abolished haloperidol-induced loss of complex I activity.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Preliminary evidence indicates that coadministration of ALA (and/or glutathione) could potentially reduce depletion of naturally occurring glutathione and other adverse side effects caused by use of haloperidol. No definitive advice or dosage recommendations can be offered given the lack of clinical trials. Physicians prescribing haloperidol, and possibly related antiemetics and antipsychotics, are advised to work in close collaboration with health care professionals trained and experienced in nutritional therapeutics and closely monitor patients choosing to use ALA (and/or glutathione) during and after

haloperidol therapy. ALA, typically at dosages of 20 to 50 mg per day, is frequently prescribed for general antioxidant protection, whereas 800 mg/day ALA and 150 mg/day glutathione are often administered in the treatment of other neurological conditions involving free-radical damage. ALA has no known toxic effects at such dosages and has never been shown to inhibit the therapeutic efficacy of haloperidol.

Irbesartan and Related Angiotensin II Receptor Antagonists

Evidence: Irbesartan (Aprovel, Avapro, Karvea).
Extrapolated, based on similar properties: Candesartan (Atacand), eprosartan (Teveten), losartan (Cozaar), olmesartan (Benicar), telmisartan (Micardis), valsartan (Diovan); combination drugs: candesartan and hydrochlorothiazide (Atacand HCT); irbesartan and hydrochlorothiazide (Avalide); losartan and hydrochlorothiazide (Hyzaar); valsartan and hydrochlorothiazide (Diovan HCT).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Increased angiotensin II activity, induction of a proinflammatory and oxidative state, and endothelial dysfunction are pathophysiological characteristics associated with metabolic syndrome; insulin resistance, obesity, hypertension, hypertriglyceridemia, and low HDL cholesterol are its clinical hallmarks. Concurrent use of ALA and irbesartan can produce an additive or synergistic response in reducing inflammation and oxidative damage in endothelial tissue. ALA's antioxidant activity may reduce endothelial tissue damage, support endothelial function, and protect insulin action through its action on oxidative stress. Irbesartan is an angiotensin II receptor (AT1 subtype) antagonist, effectively blocking the renin-angiotensin system, specifically the vasoconstrictor and aldosterone-secreting effects of angiotensin II by selectively binding to the AT1 angiotensin receptor. The mechanisms of this interaction appear to derive from the known activities of the individual agents but have yet to be fully elucidated.

Research

In a randomized, double-blind, placebo-controlled trial involving 58 patients with the metabolic syndrome, Sola et al.[17] investigated the effects of combining irbesartan and ALA on vasodilation and inflammation biomarkers. The subjects were administered irbesartan (150 mg/day), lipoic acid (300 mg/day), both irbesartan and ALA, or placebo. After 4 weeks' intervention, endothelium-dependent flow-mediated vasodilation of the brachial artery was increased by 67%, 44%, and 75% in the irbesartan, ALA, and irbesartan plus ALA groups, respectively, compared with the placebo group. Irbesartan and/or ALA administration was associated with statistically significant reductions in plasma levels of interleukin-6 and plasminogen activator-1. Similarly, levels of 8-isoprostane (a marker of oxidative stress) decreased in patients receiving irbesartan alone or in combination with ALA. No significant changes in blood pressure were observed in any of the study groups.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing irbesartan for patients with hypertension are advised to consider coadministration of ALA and to discuss this therapeutic option with the patient. Further research through well-designed clinical trials is warranted to test and refine guidelines for clinical management of such concomitant therapy. Pending conclusive research, available evidence indicates that integration of this nutrient into an existing or new therapeutic strategy for blood pressure management, glucose stabilization, atherosclerosis prevention, and cardiovascular risk reduction introduces little, if any, probability of adverse effects and is relatively inexpensive to administer.

Oral Hypoglycemic Agents and Insulin

Evidence: Glyburide (Glibenclamide; Diabeta, Glynase, Glynase Prestab, Micronase, Pres Tab).
Extrapolated, based on similar properties: Chlorpropamide (Diabinese), glimepiride (Amaryl), glipizide (Glucotrol, Glucotrol XL), insulin (animal-source insulin: Iletin; human analog insulin: Humalog; human insulin: Humulin, Novolin, NovoRapid, Oralin), metformin (Glucophage), tolazamide (Tolinase), tolbutamide (Orinase, Tol-Tab); combination drugs: glipizide and metformin (Metaglip); glyburide and metformin (Glucovance).

Interaction Type and Significance

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **4. Plausible**

Evidence Base: ▽ **Mixed**

Effect and Mechanism of Action

Numerous studies of ALA have investigated many aspects of its effect on glucose, insulin resistance, and diabetes. Theoretically, concomitant use of oral hypoglycemic agents or insulin and ALA could result in an additive or synergistic response on glucose and insulin levels.

Research

Alpha-lipoic acid and other antioxidants (e.g., vitamin C, vitamin E, *N*-acetylcysteine/NAC) may protect insulin action under oxidative stress. Animal studies have demonstrated that oral administration of ALA can prevent early glomerular injury in non–insulin-treated, streptozotocin diabetic rats. Furthermore, ALA can attenuate hyperglycemia and prevent hypertension, insulin resistance, and oxidative stress, while also preventing glomerular mesangial matrix expansion, in animal models of diabetes.[18,19] In a randomized, open, three-period crossover trial with 14 male and 10 female healthy volunteers, Gleiter et al.[20] reported finding a lack of interaction between ALA, glyburide, and acarbose. ALA did not alter glyburide pharmacokinetics to a clinically significant extent. Plasma insulin and glucose concentrations did not indicate a significant interaction between ALA and glyburide or ALA and acarbose.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The available evidence indicates that in some circumstances, concomitant use of ALA with oral hypoglycemic agents or insulin might result in an additive or synergistic response of uncertain clinical significance. The exact clinical effect has yet to be demonstrated, but the protective effects on tissues of diabetic animals strongly suggest the use of this significant

substance as an adjunctive to oral hypoglycemics and insulin in a preventive mode.

In the event that such an interaction is active, it could be therapeutically advantageous, if applied in a coordinated manner involving collaboration, close supervision, and regular monitoring involving health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics, or it might result in adverse effects of unknown severity, if physician-patient dialogue is inadequate or multidisciplinary coordination insufficient. Further research in large, well-designed human trials is warranted to confirm the efficacy of ALA as part of a comprehensive approach to the care of patients with dysglycemia, insulin resistance, and diabetes and to develop clinical guidelines for integrative therapeutics.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Anesthesia, General

Anesthesia, general

Related but evidence lacking for extrapolation: Halogenated inhalational anesthetic agents: Desflurane (Suprane), enflurane (Ethrane), halothane (Fluothane), isoflurane (Forane), sevoflurane (Sevorane, Ultane).

Administration of alpha-lipoic acid (ALA) may be beneficial after surgery as a means of facilitating metabolic breakdown of anesthesia, analgesics, and other drugs and ameliorate any residual toxic effects. Postoperative care might include 100 mg ALA orally three times daily for 2 weeks. In some cases a similar dosage for 1 week preoperatively might provide a means of reducing adverse effects in particularly sensitive individuals. However, such preemptive usage would only be appropriate with agents that would not be interfered with or prematurely broken down by ALA.

Cyclophosphamide and Vincristine

Cyclophosphamide (Cytoxan, Endoxana, Neosar, Procytox), vincristine (Leurocristine, Oncovin, Vincasar PFS).

In a rat model, Berger et al.[21] reported that pretreatment with ALA showed no negative influence on the chemotherapeutic efficacy of cyclophosphamide against transplanted sarcoma or vincristine sulfate against transplanted carcinosarcoma. ALA significantly increased median survival time and lowered the toxic effects of vincristine compared to animals treated with vincristine alone. Evidence was lacking of any significant diminution of cyclophosphamide-induced toxic effects from adjuvant treatment with ALA. Subsequently, in a mouse model, Faust et al.[22] found that ALA significantly reduced the incidence of cytotoxic effects from cyclophosphamide, particularly drug-induced diabetes. These authors hypothesized that the anti-inflammatory action and protective effect of ALA on diabetes development might be attributed to enhanced scavenging of reactive oxygen species (ROS) reducing islet infiltration and inflammation. Further research into this potential supportive interaction is warranted in light of ALA's strong safety profile and the common occurrence and relative severity of cyclophosphamide-induced adverse effects, particularly iatrogenic diabetes.

Doxorubicin and Related Anthracycline Chemotherapy

Evidence: Doxorubicin (Adriamycin, Rubex).

Extrapolated, based on similar properties: Daunorubicin (Cerubidine), epirubicin (Ellence, Pharmorubicin), idarubicin (Idamycin, Zavedos), Mitoxantrone (Novantrone, Onkotrone).

Similar properties but evidence lacking for extrapolation: Daunorubicin, liposomal (DaunoXome); doxorubicin, pegylated liposomal (Caelyx, Doxil, Myocet).

The cardiotoxicity of doxorubicin can be of rapid onset and can endure for decades, often absent cardiac complaints. In a longitudinal assessment of cardiac function in 22 patients treated with anthracycline for osteogenic sarcoma or malignant fibrous histiocytoma, Brouwer et al.[23] found systolic dysfunction in more than a quarter of the patients and diastolic dysfunction in nearly half after two decades (median, 22 years). Moreover, cardiac dysfunction was progressive, as measured at 9, 14, and 22 years. Numerous animal studies have demonstrated ALA's ability to ameliorate myocardial toxicity, nephrotoxicity, and other effects of lipid peroxidation induced by doxorubicin.[24–29] If, as suggested, ALA provides a significant protective effect against toxicity induced by doxorubicin, it may therefore improve the therapeutic index of doxorubicin. Further research in well-designed human trials is warranted to confirm the efficacy of ALA as an adjuvant therapy within a comprehensive approach to chemotherapeutics and to develop clinical guidelines for such integrative therapeutics within oncological care.

Levothyroxine, Thyroid

L-Triiodothyronine (T_3): Cytomel, liothyronine sodium, liothyronine sodium (synthetic T_3), Triostat (injection).

Levothyroxine (T_4): Eltroxin, Levo-T, Levothroid, levothyroxine (synthetic), levoxin, Levoxyl, Synthroid, thyroxine, Unithroid.

L-Thyroxine and L-triiodothyronine ($T_4 + T_3$): animal levothyroxine/liothyronine, Armour Thyroid, desiccated thyroid, Westhroid.

L-Thyroxine and L-triiodothyronine (synthetic $T_4 + T_3$): Euthroid, Euthyral, liotrix, Thyar, Thyrolar.

Dextrothyroxine (Choloxin).

In rats, ALA (7.5 mg/100 g/day) inhibited enzymatic conversion of thyroxine (T_4) to triiodothyronine (T_3).[30] ALA coadministration with T_4 also had an apparent synergistic effect on serum cholesterol, producing significantly greater depression than T_4 alone. Blood hormone levels and thyroid function tests should be monitored for this potential interaction.

NUTRIENT-NUTRIENT AND HERB-NUTRIENT INTERACTIONS

Acetyl-L-Carnitine

The combined administration of ALA and acetyl-L-carnitine improved measures of memory in rats, particularly in the older animals.[31,32] Such findings are consistent with the known pharmacological activity of both agents on neural tissue, especially mitochondrial function, and further research involving well-designed human trials appears warranted.

Biotin

Biotin synthase and lipoate synthase share a very high sequence similarity, suggesting that both enzymes are strongly mechanistically related.[33,34] Some initial animal research indicated that chronic administration of ALA may interfere with the activities of biotin-dependent liver carboxylases in rats. However, subsequent research indicates that ALA may inhibit biotin uptake in some but not all conditions involving biotin transport systems.[35] Further research is required to determine if this phenomenon occurs in humans and if so whether it is clinically significant.[36] The role biotin deficiency

might play in influencing such efficacy also deserves consideration.

Coenzyme Q10

As physiological allies within antioxidant networks, ALA, DHLA, and coenzyme Q10 facilitate, magnify, and reinforce each other's activity against ROS and oxidative damage, possibly achieving a superadditive effect of ubiquinone in combination with DHLA in preventing peroxidation of biomembranes.[37]

Copper

By chelating Cu^{2+} and other mechanisms, ALA and other antioxidants may provide significant protective activity against the free-radical damage associated with copper toxicity.[3,38-40] Pyruvate dehydrogenase is especially vulnerable to inhibition by oxygen free radicals and can play a central role in copper toxicity–induced neuronal death in Wilson's disease and possibly the pathogenesis of Alzheimer's and prion diseases.

Omega-3 Fatty Acids (Fish Oil)

Free radicals may be involved in causing toxicity in hyperoxaluric conditions. In an animal study, Lenin et al.[41] found that cellular antioxidant defenses can be increased by the coadministration of lipoate and a novel derivative, eicosapentaenoate-lipoate. Further clinical research is warranted to determine the efficacy of prophylactic treatment with ALA, eicosapentaenoic acid, and eicosapentaenoate-lipoate in preventing stone formation in the bladders of susceptible individuals.

Iron

By chelating Fe^{2+} and other mechanisms, ALA and other antioxidants may provide significant protective activity against the free-radical damage associated with iron toxicity.[3,38-40,42-49] For example, a clinical trial using the ethylenediamine salt of ALA on the indices of iron metabolism in patients with occupational pathologies found that the positive effects of ALA preparation in the patients with hyperferremia could be associated, at least partially, with normalization of iron exchange and reduction in the labile iron pool.[50]

Selenium and Milk Thistle (*Silybum marianum*)

Multiple-antioxidant therapy combining ALA with other agents, such as selenium and the herb milk thistle, is synergistic in hepatitis C therapy and may provide a cost-effective alternative approach, even in patients with a poor prognosis.[51]

Vitamin B_1 (Thiamine)

Individuals susceptible to thiamine deficiency, such as alcoholics, may derive increased benefit from concomitant vitamin B_1 and ALA. However, Gal[52] reported reversal of selective toxicity of ALA by thiamine in thiamine-deficient rats. Although no toxicity in humans has been suggested, further research into the relationships between these two important nutrients is warranted.

Vitamin E

Alpha-lipoic acid regenerates and thus extends the metabolic activity of vitamin E, particularly in the context of vitamin C administration.[3,6,53-58] Researchers have found that ALA may prevent symptoms of vitamin E deficiency, although not in the context of a vitamin E–deficient diet.[59]

Vitamin K

Vitamin K 2,3-epoxide reductase is the enzyme that recycles vitamin K back to its active form. This enzyme's activity in hepatic microsomes requires only a thiol cofactor, such as synthetic dithiothreitol (DTT). Both reduced lipoamide and reduced ALA stimulate microsomal vitamin K epoxide reduction, with kinetics comparable to those of synthetic DTT, suggesting that ALA is entirely capable of recycling oxidized vitamin K without relying on other cofactors. Thijssen et al.[60] found that hepatic microsomes contain NADH-dependent lipoamide reductase activity, which can provide reduced lipoamide for this purpose as well. These findings suggest that the vitamin K cycle obtains reducing equivalents from NADH through microsomal lipoamide reductase, and that ALA, vitamin K, and other nutritional cofactors may also provide synergistic beneficial actions in the treatment of mitochondrial disorders.[61]

The 61 citations for this monograph, as well as additional reference literature, are located under Alpha-Lipoic Acid on the CD at the back of the book.

Chondroitin Sulfate

Nutrient Name: Chondroitin sulfate.
Synonyms: Chondroitin, chondroitin sulphate, CS, CSA, CSC; ACS4-ACS6, CDS, chondroitin sulfate A, chondroitin sulfate C, chondroitin sulphate A sodium, chondroitin-4-sulfate, chondroitin-6-sulfate, chonsurid, condroitin, Condrosulf.
Related Substances: Chondroprotective agents, chondroitin sulfuric acid, GAG, galactosaminoglucuronoglycan sulfate (Matrix), glycosaminoglycan, mesoglycan (heparan sulfate-52%, dermatan sulfate-35%, heparin-8%, chondroitin sulfate-5%).

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Cisplatin Platinum chemotherapy ☼/⊕⊕	Complexing with chondroitin sulfate appears to alter pharmacokinetic properties of cisplatin and reduce nephrotoxicity without diminishing therapeutic efficacy. Consistent findings in animal and in vitro studies suggest that human trials are warranted.	Administration of cisplatin complexed with chondroitin may be beneficial. Close monitoring appropriate.
Nonsteroidal anti-inflammatory drugs (NSAIDs) ⊕⊕⊕/☼	Coadministration of chondroitin sulfate and NSAIDs may enable anti-inflammatory effect at lower drug doses. Concurrent use of chondroitin sulfate with NSAIDs appears to result in an additive or synergistic effect. More strategically, NSAIDs may promote cartilage destruction and impair cartilage repair.	Coadministration may enable decreased dose and shortened period of NSAID use.

NUTRIENT DESCRIPTION

Chemistry and Forms

Chondroitin sulfate (CS) is composed of a protein core covalently linked to complex of large-molecular-weight glycosaminoglycans (GAGs) and disaccharide polymers, large linear heteropolysaccharide chains composed of equimolar amounts of D-glucuronic acid, D-acetylgalactosamine, and sulfates in 10 to 30 repeating disaccharide units. These repeating chains of GAGs are found embedded with type II collagen fibers in cartilaginous tissue. Chondroitin sulfate structures appear in two primary forms: chondroitin sulfate A (CSA) or chondroitin-4-sulfate has a sulfate group in the 4 position of galactosamine, and chondroitin sulfate C (CSC) or chondroitin-6-sulfate has a sulfate group in the 6 position.

Physiology and Function

Chondroitin sulfate is normally synthesized endogenously and secreted by chondrocytes, but such endogenous production tends to decrease with age, thereby playing a role in the declining ability to maintain normal structure and function of joint cartilage typically associated with the aging process.

Chondroitin sulfates are widely distributed in tissues and fluids, particularly throughout connective tissue, joint cartilage, internal walls of blood vessels and skin, urinary bladder, and embryonic tissue tissues, as well as amniotic fluid, cornea, heart valves, placenta, synovial fluid, teeth, and umbilical cord. They are the most abundant GAGs in the body.

Among its several functions, CS is most well known for its central role in articular cartilage. The high concentration of CS in the collagen network provides structure and a load-bearing surface that is both tough and compliant. By absorbing water and holding nutrients, chondroitin enhances the thickness and elasticity of cartilage and increases its ability to absorb and distribute compressive forces. Chondroitin regulates formation of new cartilage matrix by stimulating chondrocyte metabolism and synthesis of collagen and proteoglycan and facilitating transport through the low-blood-flow environment. In particular, chondroitins enhance levels of hyaluronic acid, a protective fluid that lubricates the joints. Furthermore, chondroitin sulfate inhibits the degradative action of elastase and hyaluronidase, synovial enzymes that participate in inflammation and contribute to cartilage destruction and loss of joint function by breaking down cartilage matrix and synovial fluid.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Evidence from clinical trials is gradually emerging to confirm the widespread anecdotal reports of chondroitin efficacy in the treatment of musculoskeletal injuries and degenerative joint disease, such as osteoarthritis. Administration of exogenous CS supplements the naturally occurring CS in maintenance of strong, flexible cartilage and support of healthy joint function. Some clinicians and researchers studying and treating osteoarthritis (OA) refer to CS as a "symptomatic slow-acting drug for osteoarthritis (SYSADOA)." Chondroitin sulfate addresses OA symptoms by reducing pain and increasing overall mobility while also slowing the pathological process by stabilizing and possibly improving bone and joint metabolism. Reports consistently indicate that response to treatment with chondroitin may have a delayed effect (typically reaching maximal effects after 2-6 months of regular use) compared with conventional analgesics, but that the therapeutic response exhibits longer duration (typically 3 months) after cessation of treatment. Evidence from human trials has thus far not matured sufficiently to determine whether chondroitin primarily slows or halts the process of cartilage destruction and joint damage or is capable of promoting repair and regeneration of damaged cartilage and reversal of arthritic changes, and if so, under what circumstances and treatment protocols.

As a compound rich in sulfur, and thus related to glucosamine sulfate, chondroitin may help cartilage by acting in a nutritive capacity to provide raw materials for tissue repair and regeneration.

Chondroitin may also lower blood cholesterol levels, prevent atherosclerosis, and reduce the risk of heart attacks in individuals who already have atherosclerosis.

The GAGs affect how the body processes oxalate and chondroitin intake is associated with reduced risk of stone formation by reducing urinary oxalate excretion.

Historical/Ethnomedicine Precedent

Many traditional cultures have encouraged the dietary consumption of connective tissue and use of bones in soups.

Possible Uses

Alzheimer's disease, angina, anti-inflammatory, atherosclerosis, chronic venous ulcers, connective tissue injury recovery, coronary artery disease (secondary prevention), gonarthrosis, heart disease, hypercholesterolemia, hyperlipidemia, interstitial cystitis, iron deficiency anemia, joint injury rehabilitation, leukemia, malaria, myocardial infarction, nephrolithiasis (oxalate stones), osteoarthritis (OA), osteoporosis, preterm labor prevention, snoring, sprain/strain injury.

Deficiency Symptoms

Chondroitin is not considered an essential nutrient because of endogenous synthesis. Consequently, consensus is lacking for characteristics of a chondroitin deficiency.

Dietary Sources

Animal cartilage is the only dietary source of chondroitin. The precise amount and bioavailability of chondroitin in foods is unknown.

Nutrient Preparations Available

Oral chondroitin sulfate is absorbed particularly rapidly in humans when it is dissolved in water before ingestion. It is rapidly degraded during its absorption and by extensive first-pass metabolism.[1,2] The active moiety remains unknown. In a double-blind clinical study published in 1992, L'Hirondel[3] demonstrated that up to 15% of oral chondroitin is absorbed intact through the digestive tract. Subsequent research determined that approximately 12% of oral CS becomes available to the joint tissues from the blood.[4] These studies have disproved previous speculation that oral chondroitin was not efficacious because of the large size of its molecules.

Different chondroitin products can very significantly in their chemical structure, thus affecting absorption and effectiveness. Chondroitin products with physically smaller molecules (<16,900 daltons) are more likely to provide superior bioavailability.[5] Thus, low-molecular-weight (LMW) CS is preferred. Findings from clinical trials using proprietary or otherwise specific forms of CS may not be reliably extrapolated to other products.

A review of two U.S. products conducted in 2000 reported that both had lower chondroitin levels than declared on the labels; similarly, 6 of 13 glucosamine and chondroitin combination products assayed contained low chondroitin levels.[6,7]

Dosage Forms Available

Capsule (often containing CS gel), tablet; often with glucosamine sulfate and or MSM; eyedrop solutions; intravesicular bladder administration; intramuscular (IM) injection; nasal spray; topical cream.

Source Materials for Nutrient Preparations

Chondroitin sulfate was first extracted and purified in the 1960s. Commercially available forms are usually manufactured from shark, pig, or bovine cartilage or bovine trachea, or by synthesis.

Dosage Range

Adult

Dietary: No minimal dietary requirement established.
Supplemental/Maintenance: 300 mg one to three times daily.
Pharmacological/Therapeutic: 300 to 1500 mg daily, usually in divided doses, as indicated by manufacturer recommendations and use in clinical trials. A typical dosage level for osteoarthritis is 400 mg three times daily. Researchers investigating atherosclerosis have sometimes initiated therapy administering 5 g twice daily, with meals, lowering the amount to 500 mg three times daily after a few months.
Toxic: No toxic dosage level established.

Pediatric (< 18 Years)

Dietary: No minimal dietary requirement established.
Supplemental/Maintenance: Not currently recommended for children.
Pharmacological/Therapeutic: Potential use in treating musculoskeletal injuries, but specific treatment recommendations have not been established.
Toxic: No toxic dosage level established specifically for infants and children.

Laboratory Values

Serum and synovial fluid levels have been used in clinical trials. Uesaka et al.[8] concluded that "synovial fluid levels of C4S and C6S may provide useful data in assessing the pathology of OA." However, du Souich and Verges[9] found that measuring plasma concentrations of CS "allows prediction of the maximal effect (Emax) elicited by the drug and the concentration eliciting 50% of Emax (EC50)."

SAFETY PROFILE

Overview

Chondroitin sulfate is generally well tolerated at usual dosage levels, and reports of serious adverse effects are absent. Nausea may occur at intakes greater than 10 g daily. However, no clinical trials have been of sufficient duration to assess conclusively the long-term safety of chondroitin administration.

Nutrient Adverse Effects

General Adverse Effects

Rare reports of gastrointestinal (GI) effects (diarrhea, constipation, abdominal pain) and headache constitute the primary known adverse effects. Rare reports attribute edema of legs and eyelids, arrhythmia, and alopecia.

In canine experiments, McNamara et al.[10] reported significantly decreased hematocrit, hemoglobin, white blood cell (WBC) count, and platelet count after 30 days' administration of chondroitin and suggested a potential risk of internal bleeding. However, no case reports or clinical trials have reported

occurrences of bleeding in humans as a result of exogenous chondroitin intake.

Adverse Effects Among Specific Populations

A single case report describes an exacerbation of asthma attributed to use of a glucosamine-chondroitin supplement.[11]

Pregnancy and Nursing

No adverse effects have been reported. However, sufficient research-based evidence is lacking to guarantee the safety of chondroitin in pregnancy and breastfeeding. Pending conclusive findings, prudence suggests that chondroitin be avoided during pregnancy. Some commentators have suggested that the structural similarity between heparin and chondroitin is sufficient to warrant contraindication during pregnancy because heparin is contraindicated during pregnancy, except in women with protein C or S deficiency who are normally maintained on warfarin (Coumadin), which is indeed contraindicated in pregnancy, where heparin is substituted for the duration of the pregnancy.

Infants and Children

No adverse effects have been reported. However, sufficient research-based evidence is lacking to guarantee the safety of chondroitin in infants and children.

Contraindications

No qualified contraindications have been published. Out of caution, and despite a lack of substantive evidence, some commentators have suggested that individuals with bleeding problems, such as hemophilia, or temporarily at risk for bleeding during surgery or labor and delivery should avoid chondroitin. Pending conclusive findings, such speculation may deserve consideration, and chondroitin avoidance may be appropriate for short periods before and after surgery.

An emerging body of evidence suggests that exogenous CS be avoided by individuals with a history or high susceptibility of prostate cancer, breast cancer, or melanoma. Myers[12,13] reported the case of aggravated prostate cancer in an individual whose prostate cancer had been in remission until he initiated use of CS. In a review of relevant literature, Myers reported several studies that together could reasonably be interpreted to support his hypothesis that the chondroitin had exerted a tumor-promoting effect. Myers proposes that the action of CS involves formation of a complex with the protein *versican*, which along with *decorin*, is one of two proteins that CS is attached to in joint cartilage. Notably, prostate cancer cells, breast cancer cells, and melanoma cells also express versican on their surface. Thus, the introduction of exogenous chondroitin could increase levels of versican-chondroitin complex adhering to the surface of the cancer cells, facilitating their growth and metastasis.

De Klerk et al.[14,15] studied the concentration of GAGs in fetal, normal adult, and benign hyperplastic prostate tissue. They found that dermatan sulfate is the predominant GAG in the adult normal prostate, with the central zone exhibiting a slightly higher CS content than the peripheral zone and an increased CS content in benign prostatic hyperplasia (BPH).[14] Subsequently, they investigated GAGs in human prostatic cancer and observed that the concentration of CS was higher in cancerous prostate tissue than in normal prostate tissue.[15] In 1997, Ricciardelli et al.[16] noted that elevated stromal CS GAG predicts progression in early-stage prostate cancer. The following year these researchers investigated versican and decorin, two proteins CS is attached to within the prostate, and found that versican may increase the spread of cancer, whereas decorin may suppress the spread of prostate cancer.[17] Then, in 1999, they observed that elevated levels of peritumoral CS predict a higher rate of recurrence after radical prostatectomy for early-stage prostate cancer and poor prognosis. Men demonstrating a high concentration of peritumoral CS had a 47% probability of recurrence within 5 years, in contrast to 14% in the men with low CS levels.[18] These issues were further explored in an in vitro study by Sakko, Ricciardelli, et al.[19] that examined whether versican, a recognized anti–cell adhesion molecule for various mesenchymal and nerve cell types, influences prostate cancer cell adhesion to extracellular matrix components. Further research involving versican purified from human prostate fibroblast conditioned medium confirmed its antiadhesive activity for prostate cancer cells. These researchers concluded that versican is an important modulator of tumor cell attachment to the interstitial stromal matrix of the prostate, the latter being an essential step in cancer cell motility and local invasion of the prostatic stroma.

At this point, no clinical trials or epidemiological studies have specifically determined whether administration of CS is carcinogenic or likely to aggravate existing prostate carcinoma. In particular, evidence is lacking to confirm a pattern of occurrence or mechanism of action linking chondroitin preparations and the development of CS-containing versican within tumors.

Pending substantive demonstration of safety, health care professionals treating men with prostate cancer or hyperplasia are advised to recommend glucosamine sulfate as a safe and effective substitute for chondroitin or for use as a monotherapy instead of in combination with CS. Similar considerations may be warranted for patients with a history of breast cancer or melanoma. No evidence suggests, nor have cautions been raised, that glucosamine contributes to the progression of prostate or other cancers.

Precautions and Warnings

Chondroitin could have a potential, although unproven and improbable, interaction with anticoagulant medications.

INTERACTIONS REVIEW

Strategic Considerations

Chondroitin sulfate has effectively graduated from the ranks of "alternative" therapies to the realm of standard care within recent years. Starting with its role in treating musculoskeletal disorders its potential scope for therapeutic application offers a promising future, especially within the context of multidisciplinary care using an integrative model.

Degenerative joint disease, more often referred to as osteoarthritis, is characterized by the progressive loss of functional articular cartilage and represents the most common type of arthritis worldwide. For example, osteoarthritis affects more than 20 million Americans, most of whom are over 45 years of age. Although conventional pharmacological therapies may provide palliative relief for many individuals, the shortage of effective clinical approaches for addressing the underlying disease process and pathophysiological changes has frustrated both health care providers and patients grappling with this painful degenerative process. During the past decade, a body of evidence from clinical trials and experimental studies has emerged supporting the use of CS and glucosamine sulfate, often in concert. Use of these agents, usually self-prescribed by patients, has grown steadily in the United States and Europe.

These cartilage extracts are considered as drugs in European continental countries and dietary supplements in the United States and England. Although many physicians initially relegated these agents to a questionable role based on their status as "nutritional supplements," maturation of the production system to the standards of Good Manufacturing Practices is evolving to match their proven efficacy and strong safety profile. Most importantly, chondroitin has demonstrated efficacy in halting the degenerative changes within joints to produce symptomatic efficacy (e.g., in knee OA), which is complemented by the structural and symptomatic efficacy of glucosamine sulfate. Furthermore, many literature-derived data show that CS could have an anti-inflammatory activity and a chondroprotective action by modifying the structure of cartilage and increasing both the concentration of hyaluronic acid and the viscosity of synovial fluid.

Several systematic reviews and meta-analyses have described the growing body of evidence documenting the therapeutic efficacy of CS in the treatment of OA. In a systematic quality assessment and meta-analysis of 15 clinical trials in the *Journal of the American Medical Association*, researchers concluded that glucosamine and CS "demonstrate moderate to large effects, but quality issues and likely publication bias suggest that these effects are exaggerated."[20] However, in a meta-analysis of seven trials investigating efficacy of chondroitin in the treatment of knee and hip OA also published in 2000, Leeb et al.[21] reported that in patients followed to 120 or more days, "CS was shown to be significantly superior to placebo" with respect to standard indices of pain and function. They concluded that "pooled data confirmed these results and showed at least fifty per cent improvement in the study variables in the CS group compared to placebo."[21] In a subsequent paper, Richy, Reginster, and a team of investigators from Belgium and France conducted seven individual, outcome-oriented meta-analyses using 15 randomized clinical trials selected from approximately 500 studies on the basis of high methodological quality. Although noting that quality scores in the chondroitin trials exhibited a mean of only 68.4%, they concluded: "Our work provides a clear, evidence-based advance regarding the interest in the wide use of glucosamine and chondroitin as disease-modifying compounds in the treatment of knee osteoarthritis through an accurate, conservative analysis of the most reliable experiments performed until now."[22]

In a series of interviews with several leading researchers and respected clinicians in the OA field, Hungerford[23] documented the emerging consensus supporting use of chondroitin (and glucosamine sulfate) among experienced clinicians. Noting that "chondrocytes are constantly replacing and repairing their environment," particularly "reversible lesions that occur during daily activities," Schenck and Verbruggen suggested that "90% of all patients with osteoarthritis can be treated nonoperatively." However, this repair capacity decreases with age and demanding activity because both the incorporation of sulfate into proteoglycans and the capacity to synthesize new molecules and large molecule aggregates decline with age. In response to these degenerative changes, support of normal function can be achieved using a nutritive approach. Thus, Hungerford[23] stated that in treating patients with OA, he generally uses LMW "chondroitin sulfate with glucosamine for symptomatic relief" and sees a response rate of "approximately 50%." These experts and others experienced in the care of individuals with degenerative joint changes (and injury-related joint repair) consistently emphasize that this synergistic approach should be expanded whenever possible to include individualized exercise programs and nutritional support. Acupuncture, gentle joint mobilization, exercise programs, and botanical medicine represent other time-tested options of potential value in creating an evolving and personalized multidisciplinary therapeutic strategy for prevention and treatment.

NUTRIENT-DRUG INTERACTIONS

Cisplatin and Related Platinum Chemotherapy Compounds

Evidence: Cisplatin (*cis*-diaminedichloroplatinum, CDDP; Platinol, Platinol-AQ).
Extrapolated, based on similar properties: Carboplatin (Paraplatin), oxaliplatin (Eloxatin).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action

Cisplatin has a reputation as an effective antineoplastic agent, particularly against solid tumors such as testicular cancer, ovarian cancer, both small cell and non–small cell lung cancer, and head and neck cancer. However, renal, GI, and neurological toxicity limit its clinical application, with nephrotoxicity being the most common dose-limiting adverse effect. When administered as a complex, cisplatin and CS act to alter the pharmacokinetic properties of cisplatin and reduce the nephrotoxic effects usually associated with platinum-based chemotherapy.

Research

Hausheer et al.[24] investigated a variety of substances to address the fact that almost all platinum-protecting drugs have their own intrinsic toxicities, which can be additive to the toxicity of platinum-type drugs. They observed that the sulfate groups were highly favored to react with platinum species. Albertini et al.[25] demonstrated that chondroitin sulfate A (CSA, 4-sulfate) and chondroitin sulfate C (CSC, 6-sulfate) exhibited completely different physiological roles against copper-dependent oxidation of lipoprotein, probably because of the different Cu^{2+} binding ability of each form.

Subsequently, Zhang, Otagiri, et al.[26,27] conducted a series of studies exploring the application of CSA and CSC employed as to form complexes with cisplatin (CDDP) in reducing toxic effects of cisplatin monotherapy. They stated that the "purpose of the study is to apply both carboxylate and sulfate groups to form a complex via displacement of two labile chlorides of CDDP."[26] In their initial research, they "found that CSA with a mean molecular weight of 23 kDa was capable of increasing the plasma retention of CDDP while reducing its nephrotoxicity."[27] Later, using a rat model, Zhang et al.[26] compared the effects of two different doses of a cisplatin-CS complex with cisplatin monotherapy in reducing the nephrotoxic effects associated with cisplatin therapy, specifically comparing in vivo pharmacokinetics and in vitro cytotoxicity. They found that complexing cisplatin with either of two doses of chondroitin (2 and 5 mg/kg) altered the pharmacokinetic properties of cisplatin. This modified activity provided a protective effect by slowing the distribution and perfusion of cisplatin to tissues, particularly the kidneys, and reducing renal clearance while maintaining the same level of

therapeutic activity. Their conclusion stated that this study provided "evidence that the sulfated position of chondroitin sulfates really affects the stability and the disposition of the CDDP complexes. The complex prepared with chondroitin sulfate A, with a molecular weight of over 20 kDa, is superior to that prepared by chondroitin sulfate C, because of improved pharmacokinetic properties and similar pharmacological activity to native drug."[26] Such consistent findings from these preliminary animal studies indicate that further clinical studies are warranted.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The emerging body of research strongly suggests that coadministration of CS with platinum-based chemotherapeutic agents such as cisplatin has the potential to serve as a safe and effective adjuvant therapy capable of decreasing the nephrotoxic effects resulting from drug-induced oxidative damage. Well-designed randomized trials with both arms carefully stratified to have equivalent prognostic factors will be necessary to be certain that concomitant chondroitin therapy with platinum-based therapies (as well as other neurotoxic chemotherapies, e.g., taxanes, vinca alkaloids) does not compromise efficacy of the chemotherapy. When offered such therapy, patients should be informed of the preliminary work done, and that although chondroitin likely can provide protection from nephrotoxic chemotherapy, we cannot be certain at this time that it would definitely not compromise chemotherapy efficacy. This is much less of an issue when palliative chemotherapy is concerned, but when chemotherapy is given with curative intent, such as for germ cell tumors, careful monitoring of clinical response and full disclosure to the patient and their family regarding current evidence are essential. Such integrative approaches to oncology care require a high level of collaboration among health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics, usually only obtained in multidisciplinary oncology clinics.

Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

COX-1 inhibitors: Diclofenac (Cataflam, Voltaren); combination drug: diclofenac and misoprostol (Arthrotec); diflunisal (Dolobid), etodolac (Lodine), fenoprofen (Dalfon), furbiprofen (Ansaid), ibuprofen (Advil, Excedrin IB, Motrin, Motrin IB, Nuprin, Pedia Care Fever Drops, Provel, Rufen); combination drug: hydrocodone and ibuprofen (Reprexain, Vicoprofen); indomethacin (indometacin; Indocin, Indocin-SR), ketoprofen (Orudis, Oruvail), ketorolac (Acular ophthalmic, Toradol), meclofenamate (Meclomen), mefenamic acid (Ponstel), meloxicam (Mobic), nabumetone (Relafen), naproxen (Aleve, Anaprox, Naprosyn), oxaprozin (Daypro), piroxicam (Feldene), salsalate (salicylic acid; Amigesic, Disalcid, Marthritic, Mono Gesic, Salflex, Salsitab), sulindac (Clinoril), tolmetin (Tolectin).
COX-2 inhibitor: Celecoxib (Celebrex).

Interaction Type and Significance

⊕⊕⊕ **Beneficial or Supportive Interaction, Not Requiring Professional Management**

◉ **Emerging**

Effect and Mechanism of Action

In addition to supporting formation, repair, and functionality of cartilage, tendons, bone, and joints, the nutritive activity of CS can counter the tendency of NSAID therapy to impair formation and repair of connective tissue and bone and joint rehabilitation.

Research

Numerous in vivo, animal, and human studies suggest that many NSAIDs exert deleterious effects on synthesis of vasodilator prostaglandins, joint perfusion, chondrocyte and proteoglycan metabolism, bone formation, cartilage synthesis, tendon-to-bone healing, and organization in articular cartilage, especially influencing the course of osteoarthritis.[28-34]

In a 1997 discussion of the issue of coadministration of NSAIDs and CS, Towheed and Hochberg[34a] noted that these agents provided a complementary (rather than directly pharmacologically additive) effect within a comprehensive strategy for treating OA and other musculoskeletal conditions. Leeb et al.[21] conducted a meta-analysis of seven randomized, placebo-controlled and double-blind or double-dummy trials involving a total of 703 patients (372 treated with CS and 331 controls) with OA of the knee and/or hip.[3,35-40] CS treatment duration varied from 3 to 12 months and prescribed daily CS doses ranged from 800 to 2000 mg. Because of substantial differences in reporting among the studies reviewed, the underlying therapy with NSAIDs and analgesics could not be evaluated on a clear-cut, quantitative basis. These authors noted that "CS was given along with analgesics or nonsteroidal anti-inflammatory drugs, making required dosage of comedication an important factor." Thus, "all seven publications reported statistically significant reductions in consumption of NSAIDs and/or analgesics compared to baseline in the CS groups and much less marked ones for placebo." They concluded that "CS in combination with analgesics or low-dose NSAIDs is superior to analgesics or NSAIDs alone over longer periods in the treatment of OA. Moreover, a reduction of the required daily dose of analgesics or NSAIDs could be achieved." Therefore, coadministration might enable reducing dose of these medications, especially in managing pain associated with osteoarthritis, and reduce risk of adverse effects associated with prolonged NSAID use.

In a short-term in vitro culture using cartilage specimens, El Hajjaji et al.[41] found that celecoxib, a cyclooxygenase (COX-2) selective inhibitor, increased the synthesis of hyaluronan (HA) and proteoglycans (PGs) in human cartilage explants with mid-range severity of OA in a relatively dose-dependent manner. celecoxib also reduced the net loss of labeled HA and PG molecules from cartilage explants.

Jordan et al.[42] conducted a survey of 828 patients over 55 years of age with clinically diagnosed knee OA in two general-practice populations in Wessex, England, comparing conventional and complementary therapy use by a deprived urban population with that of an affluent rural population. They found a high prevalence of NSAID use, and in "the affluent population there were statistically more NSAIDs, [and] glucosamine and chondroitin sulphate were also used."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The body of available evidence clearly supports concomitant use of CS and NSAIDs as a therapeutic option of probable value in the treatment of OA and related conditions. Such an approach is well supported by consistent findings from the research literature and emerging standards of conscientious and innovative clinical practice, and it appears to offer enhanced combined efficacy at minimal risk and cost and, because of the ability to reduce NSAID dosage levels, a likelihood of reduced risk of adverse effects.

Notably, discrimination in selecting the most efficacious anti-inflammatory agent appears to be critical, since both animal and human research indicate that aspirin and acetaminophen may interfere with the activity and efficacy of concomitant glucosamine sulfate (GS). Evidence to this point, as reviewed in the Glucosamine Sulfate monograph, suggests that coadministration of ibuprofen with GS may provide a synergistic therapeutic effect and that acetaminophen should be avoided. Thus, for example, a reasonable option where the activity of an NSAID seems indicated might be combining the standard dosage of CS (400 mg) and GS (500 mg) with ibuprofen (200 mg), three times daily, with phasing out of the ibuprofen to an as needed basis when clinically improved. This long-term clinical strategy thus shifts from symptom management to maintenance, with emphasis on tissue strengthening and maximal restoration of healthy function.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Heparin and Related Anticoagulant and Antiplatelet Medications

Anticoagulants, heparin, unfractionated (UFH): Heparin (Calciparine, Hepalean, Heparin Leo, Minihep Calcium, Minihep, Monoparin Calcium, Monoparin, Multiparin, Pump-Hep, Unihep, Uniparin Calcium, Uniparin Forte).

Anticoagulants, heparinoids: Danaparoid (Orgaran), fondaparinux (Arixtra).

Related:

Anticoagulants, low-molecular-weight (LMW) heparin: Ardeparin (Normiflo), certoparin (Mono-Embolex), dalteparin (Fragmin), enoxaparin (Clexane, Lovenox), nadroparin (Fraxiparine), tinzaparin (Innohep).

Anticoagulants, oral vitamin K antagonist anticoagulants: Anisindione (Miradon), dicumarol, ethyl biscoumacetate (Tromexan), nicoumalone (acenocoumarol; Acitrom, Sintrom), phenindione (Dindevan), phenprocoumon (Jarsin, Marcumar), warfarin (Coumadin, Marevan, Warfilone).

Observations of structural similarities in the chemical composition of CS and heparin have been extrapolated into speculative claims of a potential risk of adverse interactions in the presence of anticoagulant medications such as heparin (or warfarin), as well as antiplatelet agents, and warnings that chondroitin might be contraindicated in individuals with bleeding disorders. Chondroitin sulfate is a subcomponent of the antithrombotic danaparoid, which is classified as a "heparinoid" medication. Danaparoid sodium is a mixture of glycosaminoglycuronans, heparan sulfate, dermatan sulfate, and CS, isolated from porcine or other animal intestinal mucosa. Danaparoid is devoid of a heparin fraction; its antithrombotic effect is derived primarily from antithrombin III–mediated inhibition of factor Xa and to a significantly lesser extent by inactivation of factor IIa (thrombin). Dermatan sulfate (sometimes called chondroitin B sulfate) potentiates heparin cofactor II and may prolong bleeding time but is not used in treating joint pain or degeneration. Overall, the available data suggest that CS may potentially exert a mild anticoagulant effect.[43]

Several case reports have been published describing a possible augmentation effect, as indicated by an elevated international normalized ratio (INR), in patients taking formulations containing both GS and CS while undergoing anticoagulant therapy with oral vitamin K antagonist medication.[44,45]

The limited and nonqualified nature of the available data in these published reports supports caution and indicates that further investigation through well-designed clinical trials is warranted. However, stark, generalized contraindications are not supported by the data available at this time. Health care providers treating individuals taking anticoagulant (or antiplatelet) medications are advised to caution patients against self-medication with CS and to monitor such patients in the event that CS administration is deemed clinically appropriate.

NUTRIENT-NUTRIENT INTERACTIONS

Glucosamine Sulfate

The number of studies supporting increased efficacy from concomitant administration of GS and CS in the treatment of joint pain and degenerative conditions has grown steadily in number and power. Most have found the combination more effective than either agent alone, particularly in OA treatment.[22,46-55] Although often limited by size and design, the findings from clinical trials remain consistent with known physiological function and reasonably predictable therapeutic activity.

Nevertheless, in the 4-year Glucosamine/chondroitin Arthritis Intervention Trial (GAIT) involving almost 1600 participants with documented knee OA, Clegg et al.[55,56] found that glucosamine hydrochloride (500 mg three times daily), CS (400 mg three times daily), or the combination for 24 weeks did not provide statistically significant relief (defined as a decrease in pain of at least 20%) from OA-associated pain among all subjects, compared to placebo and celecoxib (200 mg daily) as positive control. However, an analysis of the subgroup with initial moderate to severe pain (excluding those with mild pain) revealed relief with the combined nutrients at statistically significant levels compared to placebo (79.2% vs. 54.3%) or celecoxib (69.4%). Also, 60% of all subjects administered placebo reported 20% or greater pain reduction; this high response rate in the placebo group may have obscured a therapeutic response in subjects administered the glucosamine and/or CS, especially among subjects with initial mild pain. As with many similar trials, participants were allowed to use up to 4000 mg of acetaminophen daily for pain, except for the 24 hours before assessment, further confounding the data and possibly adversely affecting therapeutic response. Notably, however, resort to such "rescue" acetaminophen was relatively low, overall averaging fewer than two 500-mg tablets daily.[56,57] The pivotal clinical issue of disease progression (vs. pain relief), including joint function and regeneration, was not addressed in this study. Such elements of pathophysiology are central to the therapeutic strategy of nutritional interventions, such as those involving the sulfate compounds, and are illuminated by research demonstrating that meniscal pathology increases the risk of cartilage loss in patients with symptomatic knee OA.[58] Continued research is warranted, but changes in trial design might provide more meaningful clinical findings.

Manganese

Leffler et al.[47] conducted a 16-week, randomized, double-blind, placebo-controlled crossover trial involving 34 male subjects investigating the combined effects of glucosamine HCl (1500 mg/day), CS (1200 mg/day), and manganese ascorbate (228 mg/day) in the treatment of degenerative joint disease (DJD) of the knee or low back. They found, by several objective and subjective measures, that such short-term combination therapy "relieves symptoms of knee osteoarthritis" and "appears safe." In a 6-month, double-blind, placebo-controlled clinical trail involving 93 people with knee arthritis, Das and Hasmmand[49] found that a combination of glucosamine and chondroitin (along with manganese) was more

effective than placebo. It is not possible to determine from such studies whether or not manganese contributes additively, synergistically, or not at all to the established clinical activity of glucosamine and chondroitin.

Some sources suggest that total daily intake of manganese from foods and supplements should not exceed 11 mg, the upper limit of safety for manganese established by the Food and Nutrition Board of the U.S. Institute of Medicine.

Vitamin D; Vitamins C and E

Epidemiological studies suggest that a low serum level of vitamin D and low dietary intake of both vitamins C and E in healthy individuals 50 years of age is a predisposing factor for occurrence of knee OA at age 70.[59]

HERB-NUTRIENT INTERACTIONS

Devil's Claw

Devil's Claw *(Harpagophytum procumbens)*.

Ginger

Ginger *(Zingiber officinale)*.

Traditional patterns of use in indigenous and classic medical practice suggest efficacy of these botanicals in the treatment of OA and related joint pain and degenerative conditions. Enhanced therapeutic benefits resulting from additive or synergistic effects of combined use with CS (as well as GS) are reasonably probable based on clinical anecdotal reports and known pharmacological activity. Further clinical trials of good design, adequate size, and extended duration are warranted to investigate efficacy and establish guidelines for therapeutic application. Adverse effects caused by toxicity, at usual dosage levels in appropriate conditions, are improbable based on currently available scientific data.

The 60 citations for this monograph, as well as additional reference literature, are located under Chondroitin Sulfate on the CD at the back of the book.

Coenzyme Q10

Nutrient Name: Coenzyme Q10.
Synonyms: Coenzyme Q, coQ10, ubidecarenone; co-enzyme Q10, coQ10-alpha-cyclodextrin, coenzyme Q (50), coQ, coQ(50), co-Q10, coQ-10, 2,3 dimethoxy-5 methyl-6-decaprenyl benzoquinone, mitoquinone, Q10, ubiquinone, ubiquinone-10, ubiquinone-Q10, vitamin q10, vitamin Q10.
Related Substance: Ubiquinol (QH).
Synthetic Analog: Idebenone (water soluble).
Trade Names: Andelir, Cavamax W8/CoQ10, Heartcin, Neuquinone, Taideconone, UBTH, Udekinon.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Beta-1-Adrenoceptor Antagonists Antihypertensive medications ☼/⊕	Beta blockers and related agents inhibit, to varying degrees, coQ10-related mitochondrial enzymes in cardiac tissue. Resulting drug-induced depletion pattern can adversely affect cardiac patients who are, in general, characterized by compromised coQ10 status. CoQ10 does not appear to interfere with therapeutic action of these medications.	Coadminister oral coQ10. Monitor closely.
Chlorpromazine Thioridazine Phenothiazines ◇≈≈/☼	Phenothiazines appear to inhibit NADH-oxidase and succinoxidase, coQ10-related enzymes, and thereby contribute to pattern of adverse myocardial depressant effects associated with these agents. CoQ10 appears to mitigate adverse effects without diminishing therapeutic action of these medications.	Coadminister oral coQ10. Monitor closely.
Doxorubicin Anthracycline chemotherapy ◇≈≈/☼	Oxidative stress caused by anthracyclines often results in cardiotoxicity and other adverse effects from competitive inhibition of coQ10. CoQ10 supplementation can reduce free-radical damage and prevent anthracycline-induced cardiotoxicity. Clinical evidence is lacking to suggest coQ10 might interfere with therapeutic effect of anthracycline chemotherapy agents.	Coadminister oral coQ10. Monitor closely within context of integrative oncology care.
HMG-CoA reductase inhibitors (statins) ◇≈≈/≈≈/☼/⊕⊕	HMG-CoA reductase inhibitors lower coQ10 levels, to varying degrees, by directly interfering with coQ10 synthesis. Resulting depletion of coQ10 over time can potentially induce adverse effects on cardiac function, especially in individuals with susceptibility to or presence of chronic heart failure, but may be prevented with coQ10 coadministration, without diminishing therapeutic action of the statin. Research findings on clinical significance of statin-induced coQ10 depletion and potential benefits of coQ10 coadministration are mixed.	Consider coadministration of oral coQ10. Monitor closely within context of integrative cardiovascular care.
Sulfonylureas Oral hypoglycemic agents ☼/◇≈≈/≈≈	Hypoglycemic drugs may inhibit, to varying degrees, the coQ10 enzyme NADH-oxidase and thereby cause adverse effects on bioenergetics, ATP generation, and insulin biosynthesis. Diabetic individuals are more likely to be predisposed to compromised coQ10 status and elevated oxidative stress. CoQ10 support can mitigate drug-induced adverse effects and may enhance insulin function and cardiovascular health.	Coadminister oral coQ10. Closely monitor glucose levels.
Tricyclic antidepressants (TCAs) ◇≈≈/≈≈≈	TCAs can interfere with NADH-oxidase and succinoxidase, coenzyme Q10 enzymes, and may induce coQ10 deficiency. These actions may contribute to well-known association with cardiac adverse effects. Concomitant coQ10 administration appears to mitigate adverse effects without diminishing antidepressant activity.	Coadminister oral coQ10. Monitor closely.
Warfarin Oral vitamin K antagonist anticoagulants ?/✗/✗✗	Available clinical trial evidence does not support concerns that coQ10 might interfere with warfarin function based on structural similarities to vitamin K and several anecdotal reports. Administration of coQ10 may be therapeutically appropriate for many individuals receiving coumarin therapy. Nevertheless, gradual changes in dosage levels of any medication or nutrient is critical to maintain INR within therapeutic range.	Coadminister oral coQ10 if indicated. Monitor INR closely within context of integrative cardiovascular care.

HMG-CoA, 3-Hydroxy-3-methylglutaryl coenzyme A; *NADH*, reduced form of nicotinamide adenine dinucleotide; *ATP*, adenosine triphosphate; *INR*, international normalized ratio.

NUTRIENT DESCRIPTION

Chemistry and Form

Coenzyme Q10 (coQ10) belongs to a family of compounds known as *ubiquinones*, all of which are characterized by a functional group known as a *benzoquinone*. Ubiquinones are fat-soluble molecules with between 1 and 12 isoprene (5-carbon) units. Among the 10 naturally occurring coenzyme Q compounds, the ubiquinone found in humans is known as coenzyme Q10 because of the distinctive "tail" of 10 isoprene units (containing 50 carbons in toto) attached to its benzoquinone "head."

Physiology and Function

In humans, coQ10 is synthesized in most tissues throughout the body. Three major steps are involved in the endogenous synthesis of coQ10: (1) synthesis of the benzoquinone structure from tyrosine or phenylalanine, (2) synthesis of the isoprene side chain from acetyl coenzyme A (CoA) via the mevalonate pathway, and (3) the condensation or merging of these two structures. 3-Hydroxy-3-methylglutaryl-CoA (HMG-CoA) reductase is the critical enzyme regulating coQ10 synthesis as well as cholesterol synthesis.

Coenzyme Q is highly soluble in lipids and is found in virtually all cell membranes, as well as lipoproteins. The primary biochemical action of coQ10 is as a coenzyme for numerous enzymes in the electron transport chain, a series of oxidation-reduction (redox) reactions involved in cellular respiration, where the presence of coQ in the inner mitochondrial membrane is required for the conversion of energy from carbohydrates and fats in the synthesis of adenosine triphosphate (ATP). Within the mitochondrial electron transport chain, coQ accepts electrons from reducing equivalents generated during fatty acid and glucose metabolism and transfers them to electron acceptors. Simultaneously, a proton gradient across that membrane results when coQ transfers protons outside the inner mitochondrial membrane. When the protons subsequently flow back into the mitochondrial interior, energy is released to form ATP.

Coenzyme Q10 has dual potential to enhance energy production by bypassing defective elements of the respiratory energy production chain and through its function as an antioxidant. Coenzyme Q can exist in three oxidation states: (1) the fully reduced ubiquinol form ($CoQH_2$), (2) the radical semiquinone intermediate (CoQH), and (3) the fully oxidized ubiquinone form (CoQ). Thus, in its central role as a pro-oxidant within mitochondria, coQ10 enables aerobic energy gain, promotes unilateral proton accumulation, and generates reactive oxygen species (ROS) involved in physiological signaling. Ubiquinone can execute reversible addition of single electrons and protons. Lysosomal membranes critical to cellular detoxification and recycling contain particularly high concentrations of coQ. Recent research indicates that lysosomal ubiquinone maintains the optimal pH for cellular recycling through its double function as proton translocator and radical source, particularly under certain metabolic conditions such as an acid pH. Alternately, a range of research demonstrates a pervasive and potent role of coenzyme Q10 in protecting membranes and DNA from oxidative damage from free radicals directly and through suppression of the formation of oxidized lipids and the consumption of alpha-tocopherol. As a lipophilic molecule, the reduced form of coQ, $coQH_2$, along with enzymes that are capable of reducing oxidized coQ back to $coQH_2$, is particularly concentrated in mitochondrial cell membranes, where it acts as a key cellular antioxidant and provides protection against free-radical damage. However, the type of biomembrane where ubiquinone exerts its free-radical, chain reaction–breaking activity can significantly affect this action's efficiency. Furthermore, $coQH_2$ regenerates alpha-tocopherol radicals back to the chain-breaking (i.e., antioxidant) form of vitamin E and thereby further contributes to the control of lipid peroxidation. This ability to counteract oxidative stress is particularly evident in its support of healthy cardiac tissue and its protection of endothelial function. Thus, coQ10's unique chemistry enables it to function both as a pro-oxidant and as an antioxidant.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Coenzyme Q10 can be synthesized in vivo by all living organisms, including humans, and thus is not defined as a vitamin. However, in some situations, the need for coQ10 may surpass the body's ability to synthesize it, so it may be regarded as "conditionally essential." CoQ10 is well absorbed by oral administration, as evidenced by significant increases in serum, plasma, and lipoprotein concentrations of coQ10 after oral intake.[1,2] However, evidence from animal and human research is mixed as to the degree to which oral intake elevates levels in various target tissues, and how that effect might vary depending on state of health, influence of aging, and presence of dysfunction, depletion, or pathology in particular tissues and systems.[3-7]

In 1958, Professor Karl Folkers elucidated the chemical structure of coQ10 and noted its potential in the treatment of cardiovascular disease. However, his employer, Merck, chose to sell the formula and patent to a Japanese firm in favor of promoting Diuril, a new product at the time aimed at the cardiovascular drug market. Thus, although coQ10 developed a strong presence in medical and supplement markets in Japan, its entry into clinical use in the United States has been delayed but is steady growing.

Possible Uses

Alzheimer's disease, angina, arrhythmia, breast cancer, cardiac bypass surgery, cardiomyopathy, cardiovascular disease, cerebellar ataxia (familial), chemotherapy support, chronic fatigue, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), diabetes mellitus, diastolic dysfunction, fibromyalgia, gingivitis, human immunodeficiency virus (HIV) support, Huntington's disease, hypertension, immune deficiencies, insulin resistance syndrome, ischemia, lung cancer, male infertility, mitochondrial diseases, mitral valve prolapse, muscular dystrophies, myocardial infarction, neurodegenerative diseases, Parkinson's disease, periodontal disease, prostate cancer, renal failure, rhabdomyolysis.

Oral administration may also enhance aerobic capacity and muscle performance, especially in sedentary and elderly individuals. Conclusive evidence from large clinical trials has yet to be carried out to investigate this proposed action.

Deficiency Symptoms

The deficiency pattern associated with coQ10 has not been clearly defined, and it is widely assumed that endogenous production and a varied diet provide adequate coQ10 for most individuals. A deficiency may result from impaired synthesis caused by nutritional deficiencies, acquired defect in synthesis or utilization, or increased tissue needs resulting from illness. Most coQ10 in humans is internally synthesized. Genetic defects in coQ10 synthesis and metabolism are considered rare at this time. Deficiency can be caused or aggravated by depletion or deficiency of any of the many nutrients required within this 17-stage synthetic pathway, including riboflavin (vitamin B_2), niacinamide (vitamin B_3), pantothenic acid (vitamin B_5), pyridoxine (vitamin B_6), cobalamin (vitamin B_{12}), folic acid, vitamin C, and several trace elements. As might be expected, given the central role of the HMG-CoA reductase enzyme in the coQ10 synthetic pathway, HMG-CoA reductase inhibitors ("statins"), which are widely prescribed for management of dyslipidemias and cardiovascular disease,

have been implicated as an iatrogenic cause of coQ10 deficiencies.

CoQ10 concentrations in various tissues decline with advancing age, and elderly individuals are known generally to have lower levels of coQ10.[8,9] Likewise, researchers have observed that the patient populations exhibiting many of the conditions coQ10 is used to treat more often demonstrate low levels of coQ10; these include cardiomyopathy, gingivitis and periodontal disease, heart failure, and HIV/AIDS. Many researchers and clinicians consider at least a CHF subset to represent a coQ10 deficiency disease, to a significant degree. Decreased plasma levels of coQ10 have also been observed in individuals with diabetes and cancer. Lastly, individuals with the genetic polymorphisms called the LPL and NQO1 genotypes exhibit decreased coQ10 redox ratios, reflective of impaired ability to convert ubiquinone to ubiquinol.[10]

Dietary Sources

Coenzyme Q10 is widely distributed in foods but in such small amounts that extraordinary serving sizes would be required to obtain intake levels typically provided by commercial preparations (e.g., 100 mg daily).

Organ meats (e.g., heart, liver), meat, poultry, and fish are the richest dietary sources of coenzyme Q10. Nuts provide relatively high levels, as do soybean and canola oils. Vegetables, fruits, eggs, and dairy products contain moderate levels of coQ10, with broccoli and spinach being relatively richer.

Studies in Denmark conducted during the 1990s found that average dietary intake of coQ10 was 3 to 5 mg per day.[11,12] Overall, dietary sources appear to provide most individuals with less than 10 mg/day. Foods are estimated to provide an average of 25% of plasma coQ10 in most individuals. Boiling appears to have little adverse effect, but frying destroys 14% to 32% of coQ10 in foods thus prepared. The precise dietary contribution to plasma coQ10 concentration is unknown in any given individual but is estimated to be approximately 25%.

Nutrient Preparations Available

Microcrystalline cellulose-coQ10 complex.

Complexing coenzyme Q10 with alpha-cyclodextrin may enhance bioavailability of coQ10 by approximately 35% compared to a microcrystalline cellulose-coQ10 complex.[13]

Ubiquinol (QH) is the converted active form of coQ10. The conversion rate of coQ10 (ubiquinone) to ubiquinol tends to decline with age, rendering lowered serum levels of ubiquinol. Furthermore, LPL and NQO1 genotypes are associated with impaired ability to conduct this conversion.[10] However, outside the body, ubiquinol is extremely unstable without certain stabilizing procedures because it will convert to coQ10 on exposure to oxygen.[14] Since ubiquinone must be reduced to become active, oral ubiquinol may provide bioavailability up to eight times as great as that of oral ubiquinone.

Dosage Forms Available

Powder-filled hard-shell capsule, soft-gel capsule, liposomal spray, tablet, chewable wafer.

Oral coenzyme Q10 should be taken with a meal with some fat content since it is fat-soluble. Absorption decreases in the absence of lipid. Some experts suggest taking coQ10 with a small amount of olive oil to increase absorption. There is some evidence that coQ10 in oil suspension provides better bioavailability than granular form.[15-17] Chewable forms may also provide greater bioavailability than capsules or tablets.

Source Materials for Nutrient Preparations

Yeast fermentation, or semisynthetic process.

Kaneka Corporation of Japan, which is the only company to use yeast fermentation in the production of coQ10, produces the natural all-*trans* Q, which is identical to the coQ10 occurring in nature and has succeeded in obtaining "generally recognized as safe" (GRAS) status from the U.S. Food and Drug Administration (FDA).[18]

Dosage Range

Adult

Dietary: No level has been established for optimal dietary intake of coenzyme Q10.

Supplemental/Maintenance: 25 to 60 mg twice daily.

Pharmacological/Therapeutic: Ranging from 30 to 60 mg twice daily to 50 to 100 mg two to three times daily, depending on condition and in concert with a health care professional trained in nutritional therapies. Daily dosage levels of 300 to 600 mg have been used in clinical and research settings in the treatment of conditions such as severe cardiovascular disease and advanced breast cancer. Administration of 60 to 100 mg per day will usually double plasma levels of coQ10 in adults. Evidence indicates that oral intake does not impair endogenous coQ10 synthesis.

Toxic: None established.

Pediatric (< 18 Years)

Coenzyme Q10 is usually not prescribed for infants or children.

Laboratory Values

Plasma and lymphocyte coenzyme Q10 and coenzyme $Q10H_2$ levels.

SAFETY PROFILE

Overview

All available evidence indicates that coenzyme Q10 is generally safe. No significant adverse effects or toxicities have been reported as being associated with oral intake of coQ10. CoQ10 in doses up to 900 mg daily is safe and well tolerated in healthy adults for 4 weeks.[19] Even continued doses of 600 mg/day for 30 months and 1200 mg/day for up to 16 months have not been associated with significant adverse effects.[20,21]

Nutrient Adverse Effects

General Adverse Effects

Occasional reports of mild nausea, gastrointestinal (GI) discomfort, anorexia, or skin eruptions have been reported with oral intake of coQ10. Other reported adverse effects include fatigue, insomnia, headache, dizziness, irritability, photosensitivity, dyspepsia, vomiting, diarrhea, dermatitis, or flulike symptoms. Reported adverse effects typically receded when oral coQ10 was stopped or dosage levels or format were modified. Dividing daily intake into two or three dosages may eliminate adverse effects, especially if more than 100 mg/day is being used.

Pregnancy and Nursing

Adverse effects are not predicted, and reports are lacking. However, the lack of controlled studies involving pregnant or lactating women precludes claims of safety and suggests that oral intake should be avoided during such life cycles.

Infants and Children

Adverse effects are not predicted, and reports are lacking. CoQ10 administration is not recommended unless otherwise indicated as essential.

Contraindications

No contraindications have been established for coQ10.

Precautions and Warnings

No precautions or warnings are known at this time for healthy individuals. Individuals with CHF or other serious cardiovascular conditions should only discontinue coQ10 under the supervision of the prescribing health care professional; withdrawal of coQ10 intake could potentially contribute to relapse.

Cautions have been voiced regarding coQ10 use by individuals with diabetes, hypoglycemia, hypertension, or liver disease. Evidence to substantiate clinically significant adverse events is limited. Supervision and appropriate monitoring are usually adequate in most cases.

INTERACTIONS REVIEW

Strategic Considerations

The primary clinical uses of coenzyme Q10 supported by human trials are in the treatment of CHF, angina pectoris, mitochondrial encephalopathies, mitochondrial cytopathies, chronic myalgic conditions, dystrophies, fibromyalgia, and Parkinson's disease. In such conditions characterized by mitochondrial dysfunction, the functions of coQ10 in mitochondrial bioenergetics and protection against oxidative stress appear to be paramount. CoQ10's strong antioxidant activity also enables it to function as an effective therapeutic ally when administered in conjunction with medications, such as doxorubicin, that cause adverse effects as a result of inducing oxidative damage. Virtually all antioxidants are capable of functioning as pro-oxidants, either when present in overwhelming quantity (e.g., high-dose intravenous ascorbate) or when present with inadequate antioxidant network partners in an environment of high oxidative stress (e.g., smokers with poor dietary antioxidant intake who are supplemented with synthetic beta-carotene). Perhaps the unique aspect of coQ10 is that it functions physiologically both as a pro-oxidant and antioxidant and can be regenerated back to its reduced or antioxidant form through normal cellular enzymatic processes.

Many pharmacological agents inhibit coQ10 synthesis, interfere with its function, and induce coQ10 deficiency states. In such circumstances, coadministration of coQ10 can prevent or reverse adverse drug effects, often in a manner that enhances therapeutic efficacy and improves clinical outcomes. In these situations, coQ10 carries no significant risks, and controversy as to its use is minimal.

Coenzyme Q10 is most widely used in the prevention and treatment of heart disease, more recently incorporated into acute cardiac care. For example, in an innovative placebo-controlled randomized trial involving 49 patients, Damian et al.[22] found that combining liquid coQ10 (250 mg followed by 150 mg three times daily for 5 days) with mild hypothermia immediately after out-of-hospital cardiac arrest and cardiopulmonary resuscitation (CPR) appears to improve survival and may prevent reperfusion injury and neurological damage in survivors. The astroglial protein S100 is an established biochemical marker of central nervous system (CNS) injury. Mean serum S100 protein 24 hours after CPR was significantly lower in the coQ10 group (0.47 vs. 3.5 ng/mL). Three-month survival in the coQ10 group was 68% versus 29% in the placebo group, and nine coQ10 patients survived with a Glasgow outcome scale of 4 or 5 (vs. five placebo patients). As for chronic cardiovascular conditions and attendant mortality risk, evidence is not unanimously in support of its efficacy, but as part of a lifestyle that includes regular exercise and a healthy diet (particularly omega-3 oils), coQ10 may help significantly decrease cardiovascular risk.[23] In particular, chronic CHF has reached epidemic proportions and is the single most common cause for hospitalization among individuals over age 65 in the United States; in more than half these patients, impaired left ventricular (LV) diastolic function plays a major role. CoQ10 appears to provide particular benefit in reversing diastolic impairment, including adverse effects on LV diastolic function associated with atorvastatin therapy.[24] This therapeutic action, as well as the broader role of coQ10 in the treatment of chronic cardiovascular conditions, leads directly into what may become a major controversy within medicine.

The issue of the interaction between statin drugs and coenzyme Q10 presents some of the most complex and timely clinical issues affecting coQ10 and its role in human health. HMG-CoA reductase inhibitors have demonstrated important and substantial cardiovascular clinical benefits, including reducing mortality; however, the impact of coQ10 depletion with long-term statin therapy (≥20 years) is only beginning to be considered in a substantive manner, particularly concerning patients with heart failure. Nevertheless, in the first clinical research addressing some of these concerns, Go et al.[25] conducted a propensity-adjusted cohort study of all-cause death and hospitalization for heart failure during a median of 2.4 years of follow-up after initiation of statin therapy. They reported that among "adults diagnosed with heart failure who had no prior statin use, incident statin use was independently associated with lower risks of death and hospitalization among patients with or without coronary heart disease." Although encouraging, the short duration of follow-up in this study precludes any substantive conclusions regarding long-term safety of statin therapy.

The medical literature currently portrays statin therapy as a virtual "panacea" for prevention and treatment of cardiovascular conditions (and a multitude of other pathologies), but the parameters of the statin discussion have yet to expand beyond cholesterol and inflammation and incorporate comprehensive functional assessment of all risk factors. In a paper with potentially disturbing implications, Getz et al.[26] discussed the issue of estimating the high-risk group for cardiovascular disease in a well-defined Norwegian population according to European guidelines and the systematic coronary risk evaluation system. They raised concerns regarding the efficacy of applying the current cholesterol reduction goals (of total cholesterol below 180 mg/dL) being established as public policy in Europe and the United States. They noted that, in Norway, one of the world's healthiest countries, 85% of the men and more than 20% of the women over age 40 would need to be treated for high cholesterol under the American recommendations. Thus, in this population with relatively low rates of heart disease, "implementation of the 2003 European guidelines on

prevention of cardiovascular disease in clinical practice would classify most adult Norwegians at high risk for fatal cardiovascular disease."[26] These observations prompted provocative responses in the scientific literature questioning the necessity, safety, and prudence of broad-based implementation of aggressive lipid-lowering standards. In particular, Ravnskov et al.[27] pointed out that application of these recommendations would result in the majority of the world's adult population being treated with statin drugs; to which they added, "As the risk to benefit ratio for a more drastic lowering of low density lipoprotein cholesterol is unknown, we question the wisdom of this advice." Notably, May et al.[28] found that a total cholesterol level approaching 200 mg/dL is associated with higher survival in patients with heart failure than levels below 140 mg/dL.

Paradoxical evidence showing both reduced cardiovascular risk, including heart attack and stroke, and stress on cardiac tissue induced by the inherent action of HMG-CoA reductase inhibitors has yet to withstand the test of time over decades. Although 20 years may be required for ongoing inhibition of endogenous ubiquinone synthesis resulting in mitochondrial interference and diastolic dysfunction to manifest as impaired hepatic, neurological, and cardiac dysfunction or frank cardiomyopathy resulting in chronic CHF, long-term statin use could represent a significant iatrogenic risk factor for some patients, particularly those with baseline coQ10 levels that are suboptimal or compromised by aging, malnutrition, drug depletions, genotypic susceptibility, and other adverse influences. Thus, for example, Tsivgoulis et al.[29] found that patients with asymptomatic neuromuscular disorders may have their condition precipitated by statin use.

Although statin therapy may reduce inflammation, as reflected by reduced C-reactive protein (CRP) concentrations, other critical cardiovascular risk factors such as lipoprotein(a), homocysteine, and fibrinogen are not modified to any significant degree by inhibition of HMG-CoA reductase. Moreover, preliminary research indicates that hypotheses of reduced atherosclerosis and calcific aortic stenosis through aggressive lipid-lowering therapies using statins may have been premature and overly optimistic in the face of mixed findings; in fact, statins appear to block the beneficial effects of exercise on intimal thickening.[30,31] Likewise, in the IDEAL study comparing high-dose atorvastatin with usual-dose simvastatin for secondary prevention after myocardial infarction (MI), Pedersen et al.[32] found that although aggressive lipid lowering significantly reduced the risk of other composite secondary endpoints and nonfatal acute MI, intensive lowering of low-density lipoprotein (LDL) cholesterol did not reduce coronary death or cardiac arrest with resuscitation, and that there were no differences in cardiovascular or all-cause mortality.

Thus far, the potential for integrative clinical strategies based on synergistic activities has been neglected and may be most deserving of thorough investigation. A thorough review of the literature of statin therapy that incorporates a frank appraisal of risk factors suggests that the growing enthusiasm for statin drugs over the past decade may eventually succumb to a harsh realization that they are appropriate for a relatively select patient population, specifically those with severe and recalcitrant hypercholesterolemia for whom other therapies have proved ineffectual. Notably, the issue of individual pharmacogenomic variability influencing efficacious or adverse responses to statin therapy is only beginning to be considered.[33] Furthermore, until continued concerns about neuropathies, skeletal myopathies, and cardiomyopathies known or suspected to be associated with long-term statin therapy, as well as their potential for enhancing growth of subclinical malignancies through angiogenic and possibly immunomodulating mechanisms, are more fully investigated, the use of these widely prescribed, arguably overprescribed, medications should be more carefully considered, given the paucity of long-term studies of these agents, which, once instituted, will often be consumed for the lifetime of most patients. For example, in a retrospective case-control study, Wilke et al.[34] found that CYP3A genotype was associated with increased severity of atorvastatin-induced muscle damage, but not an increased risk for development of such adverse effects, as indicated by elevated serum creatine kinase (CK) levels. Thus, individuals who were homozygous for CYP3A5*3 demonstrated greater serum CK levels than patients who were heterozygous for CYP3A5*3, when concomitant lipid-lowering agents (gemfibrozil with or without niacin) were sequentially removed from the analysis. Similarly, in comparing nine haplotypes in the gene that carries the code for HMG-CoA reductase within both Caucasian and African Americans, Krauss et al.[35] found that treatment with simvastatin (40 mg) demonstrated significant genetic differences in statin response in lowering LDL cholesterol levels. Consequently, individuals who have a genetic problem with metabolizing statins could have a larger depletion of coQ10 (because of a higher level of the statin drug) and thus could have more problems. conversely, individuals who tolerate statins better may be metabolizing them faster, and thus their Q10 may not become as depleted. Moreover, half of all individuals who have heart attacks do not have hypercholesterolemia.

Meanwhile, other methods of cardiovascular disease risk reduction, such as a healthy and balanced diet, regular exercise, and omega-3 fatty acid supplementation, should be pursued vigorously as a coordinated broad response to multiple risk factors. In such an integrative approach, for example, the therapeutic benefits of statin therapy can be complemented or enhanced through coadministration of fish oil or L-carnitine.[36-43] Nevertheless, when Studer et al.[23] conducted a review of data on the efficacy and safety of different antilipidemic agents and diets on mortality, they found that fish oil and statins were the most effective interventions for lowering cardiac mortality risk, fish oil being superior to statin therapy in terms of lowering all-cause mortality, despite very modest effects on lipids.

However, other evidence has emerged that could complicate the picture. In a 6-year, randomized, controlled trial involving 140 middle-aged men, Rauramaa et al.[30] found that men undergoing statin treatment are significantly less likely to exhibit benefit from exercise in slowing atherosclerosis than those exercising but not taking statins. Intermittent exercise enhances coQ10 biosynthesis, resulting in higher coQ10 levels, and this could be a factor in the well-known health benefits of exercise. The findings from this study suggest that statins may neutralize the beneficial effect of exercise, at least in part, through their blocking of coQ10 biosynthesis. Levy and Kohlhaas[44] conducted a review of studies examining the effects of statin drugs, prescribed for reduction of cholesterol levels, on plasma concentrations of coQ10 and considerations regarding coadministration of coQ10 and concluded that "statin drug therapy does indeed reduce blood concentrations of coenzyme Q10." However, the authors determined that "due to the small number and dissimilar nature of studies available, the ability of the reviewers to draw any strong conclusions was limited." Nevertheless, "results from isolated studies suggest that statin drugs may induce mitochondrial dysfunction." Furthermore, "limited data suggest

that supplementation with coenzyme Q10 may be beneficial in patients taking statin drugs who 1) have a family history of elevated cholesterol levels, or 2) have a family history of heart failure, or 3) are over 65 years of age. Further studies investigating the effects of statin drugs on the development of myotoxicity are warranted, particularly among high-risk populations."[44] Continued research is needed to investigate the long-expressed hypothesis that many of the other adverse effects associated with statins derive from its interference with coQ10 synthesis and function.

Administration of coQ10 alone or in conjunction with other agents, as part of an integrative therapeutic strategy, offers significant potential for enhancing clinical outcomes in individuals with a range of cardiovascular conditions. In particular, numerous researchers and clinicians have reported many cases of extraordinary clinical improvement in individuals with conditions such as CHF in which the expected progression is characterized by steady worsening and morbidity within 2 years under conventional therapy. At the least, incorporation of coQ10 into the therapeutic repertoire presents an opportunity to correct myocardial deficiency of coQ10 and enhance synthesis of coQ10-requiring enzymes, thereby extending the duration and enhancing the quality of life of such patients.

NUTRIENT-DRUG INTERACTIONS

Beta-1-Adrenoceptor Antagonists (Beta-1-Adrenergic Blocking Agents) and Related Antihypertensive Medications

Evidence: Metoprolol (Lopressor, Toprol XL), propranolol (Betachron, Inderal LA, Innopran XL, Inderal).
Extrapolated, based on similar properties: Acebutolol (Sectral), atenolol (Tenormin); combination drugs: atenolol and chlorthalidone (Co-Tendione, Tenoretic); atenolol and nifedipine (Beta-Adalat, Tenif); betaxolol (Kerlone), bisoprolol (Zebeta), carteolol (Cartrol), esmolol (Brevibloc), labetalol (Normodyne, Trandate); metoprolol combination drug: metoprolol and hydrochlorothiazide (Lopressor HCT); nadolol (Corgard), nebivolol (Nebilet), oxprenolol (Trasicor), penbutolol (Levatol), pindolol (Visken); propranolol combination drug: propranolol and bendrofluazide (Inderex); sotalol (Betapace, Betapace AF, Sorine), timolol (Blocadren).
Similar properties but evidence lacking for extrapolation: Other antihypertensive drugs.

Effect and Mechanism of Action

Coenzyme Q10 plays a central role in energy production within the mitochondria of all cells but most critically in muscle cells, especially those of the heart. Propranolol and some other beta blockers inhibit, to varying degrees, enzymes in cardiac muscle, particularly NADH-oxidase and succinoxidase, that are dependent on coQ10 and indispensable for the bioenergetics of the myocardium.[45,46] Kishi et al.[47] reported that adrenergic blockers for beta receptors inhibited mitochondrial coQ10 enzymes to varying degrees.

Research

Kishi, Kishi, Folkers, et al.[46-49] have demonstrated with both in vitro and human studies and through reviews of the scientific literature that individuals with myocardial failure (dilated and restrictive cardiomyopathy and alcoholic heart disease) exhibit significantly decreased coQ10 levels compared to those with healthy myocardial tissue. Further, a strong association has been observed between the severity of the pathology and the degree of coQ10 deficiency.[46] Conversely, enhancement of coQ10 levels in the myocardium appears to counteract energy deficiency and reduce the tendency to and severity of myocardial dysfunction.

A range of antihypertensive medications have exhibited inhibitory effects on enzymes containing coQ10 in assays using mitochondrial preparations from beef myocardium.[47] Among beta blockers, propranolol demonstrates the most active inhibition of NADH-oxidase. Researchers have reported that adverse reactions related to depressed myocardial function associated with propranolol occurred in approximately 10% of 268 hospitalized patients receiving propranolol; adverse effects were reported at dosage levels as low as 30 mg daily or less.[47] In vitro research indicates that metoprolol is approximately 25% as inhibitory as propranolol; clonidine and hydralazine (both alpha-adrenergic blockers) exerted similar levels of effect. Timolol showed negligible inhibition of NADH-oxidase and exerted pharmacologically low cardiac-depressant effects. Five alprenolols showed inhibition that approached that of propranolol. The l-isomer of alprenolol showed weak inhibition of another coQ10 enzyme, succinoxidase, but the other beta blockers were essentially noninhibitory to this enzyme.[48]

The common pattern of fatigue associated with beta-blocker drugs, particularly in the elderly and individuals with preexisting coQ10 deficiency, may derive from diminished myocardial contractility, decreased cardiac output, and other coQ10-related depression of myocardial function.[47] In an open study of 40 patients in severe heart failure (classes III and IV), almost two-thirds showed objective and subjective improvement when treated with 100 mg of coQ10 daily. Individuals with hypertension demonstrate coQ10 deficiencies regardless of whether or not they are taking antihypertensive agents.[47] In a small open study, three of five subjects taking propranolol complained of general malaise, whereas none of seven subjects receiving both propranolol and coQ10 reported similar adverse effects.[49] Hamada et al.[50] found that adverse effects on myocardial contractility (and coQ10 levels) associated with propranolol therapy in hypertensive patients were reduced when 60 mg of coQ10 daily was integrated into the treatment plan. In parallel research, Takahashi et al.[51] conducted a trial with 16 glaucoma patients in which they coadministered coQ10 (90 mg/day) during treatment with timolol eye preparation for 6 weeks. They reported that this complementary therapeutic approach reduced timolol-induced cardiovascular adverse effects while preserving intended effects on intraocular pressure.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing beta blockers or related antihypertensive medications are advised to discuss adverse effects associated with these medications and the potential compensatory benefits of concomitant coQ10. Nutritionally oriented physicians and other health care providers often prescribe coQ10 for patients with cardiovascular conditions, or to prevent the occurrence of such in those concerned with or predisposed to such diseases. Therapeutic dosages of coQ10 for cardiovascular conditions range from 50 mg daily to 100 mg or more

three times daily; such dosage levels would be appropriate within the context of conventional treatment of hypertension with beta blockers and most other antihypertensive medications.

Chlorpromazine, Thioridazine, and Related Phenothiazines

Evidence: Chlorpromazine (Largactil, Thorazine), thioridazine (Mellaril).
Extrapolated, based on similar properties: Acetophenazine (Tindal), fluphenazine (Modecate, Permitil, Prolixin, Prolixin Decanoate, Prolixin Enanthate), mesoridazine (Serentil), methotrimeprazine (levomepromazine; Nozinan), pericyazine (Neuleptil), perphenazine (Trilafon); combination drug: perphenazine and amitriptyline (Etrafon, Triavil, Triptazine); prochlorperazine (Compazine, Stemetil), promazine (Sparine), promethazine (Phenergan, Promacot, Promethegan), propiomazine (Largon), thiethylperazine (Torecan), thioproperazine (Majeptil), trifluoperazine (Stelazine), triflupromazine (Vesprin).

Interaction Type and Significance

◇≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**

☼ **Prevention or Reduction of Drug Adverse Effect**

Adverse Effect Probability: **3. Possible**
Evidence Base: ◉ **Emerging**

Nutrient Benefit **3. Possible**
○ **Preliminary**

Effect and Mechanism of Action

Phenothiazines are associated with adverse effects on cardiac function in some individuals. In vitro, phenothiazines inhibit NADH-oxidase and succinoxidase. Furthermore, chlorpromazine has strong alpha-adrenergic blocking activity and can induce orthostatic hypotension.

Research

Folkers, Kishi, and other researchers demonstrated that thioridazine and related phenothiazine agents can induce adverse changes in cardiac activity in some individuals. Inhibition of myocardial respiration, particularly NADH-oxidase and succinoxidase, by phenothiazines and other psychotherapeutic drugs contributes significantly to these adverse myocardial depressant effects. Research indicates that coadministration of coQ10 can prevent or reverse these changes, but conclusive evidence from large, well-designed clinical trials is lacking.[49,52]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Current use of phenothiazines has largely moved beyond the more obvious adverse effects and nutrient depletion patterns associated with prescribing patterns of prior decades. However, pending further research, physicians prescribing thioridazine and related phenothiazine agents are advised to inform patients of potential adverse effects and the possible benefit of reducing adverse effects through coadministration of coenzyme Q10. A typical oral dose of 30 to 50 mg twice daily would generally be appropriate but should be tailored to the particular characteristics and evolving needs of the individual patient. No evidence is available and no suggestion has been made that such nutrient support introduces any significant risk directly or through interference with the medication.

Doxorubicin and Related Anthracycline Chemotherapy

Evidence: Doxorubicin (Adriamycin, Rubex).
Extrapolated, based on similar properties: Daunorubicin (Cerubidine), epirubicin (Ellence, Pharmorubicin), idarubicin (Idamycin, Zavedos), mitoxantrone (Novantrone, Onkotrone).
Similar properties but evidence lacking for extrapolation: Daunorubicin, liposomal (DaunoXome); doxorubicin, pegylated liposomal (Caelyx, Doxil, Myocet).

Interaction Type and Significance

◇≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **1. Certain**
Evidence Base: ● **Consensus**

Effect and Mechanism of Action

Anthracyclines generate free radicals that cause oxidative damage, particularly microsomal lipid peroxidation, through an iron-dependent process, which results in cardiotoxicity and adverse effects on other tissues. Doxorubicin also causes several other adverse effects, including (1) reduction of the coQ10 content within mitochondrial membranes, (2) inhibition of mitochondrial biosynthesis of coQ10, and (3) inhibition of mitochondrial synthesis coQ10-dependent enzymes, particularly succinoxidase and NADH-oxidase. Evidence indicates that such interference with coQ10 metabolic processes and depletion of coQ10 constitutes a major factor in the acute and chronic adverse effects associated anthracyclines, particularly doxorubicin-induced cardiotoxicity.[52-54]

The acute and chronic forms of cardiomyopathy induced by doxorubicin appear to derive from its specific effects on coQ10 synthesis and function, both immediate interference and metabolic sequelae. A single dose of doxorubicin causes inhibition of respiratory enzymes and rapidly induces a characteristic, acute cardiotoxicity.[55] Furthermore, not only can the cardiotoxicity of doxorubicin be of rapid onset, but it also can endure for decades, often absent cardiac complaints. Thus, in a longitudinal assessment of cardiac function in 22 patients treated with anthracyclines for osteogenic sarcoma or malignant fibrous histiocytoma, Brouwer et al.[56] found systolic dysfunction in more than a quarter of the patients and diastolic dysfunction in almost half after two decades (median, 22 years). Moreover, cardiac dysfunction was progressive, as measured at 9, 14, and 22 years.[56] This effect, sometimes reversible, appears to result, at least in part, from competition between the drug and coQ10, both of which contain a quinone group, for the enzymatic sites of the coenzyme. Doxorubicin may also cause enzyme inhibition through oxidation of coQ10, directly and through doxorubicin-induced ROS. Subsequent depletion of coQ10, with attendant loss of its physiological functions in electron transport and mitochondrial respiratory energetics, plays a major role in the loss of mitochondrial integrity and necrosis of cardiac myocytes characteristic of chronic doxorubicin-induced cardiotoxicity. Thus, coQ10 exhibits a unique ability to reduce free-radical formation induced by doxorubicin and to prevent resultant toxicity, particularly the chronic form; other antioxidants, such as vitamin C and alpha-tocopherol, do not provide a similar protective effect.[57]

Cardiac toxicity is similar between equipotent doses of doxorubicin and daunorubicin, slightly lower for epirubicin, and only one-sixth that of doxorubicin for equipotent doses of mitoxantrone. Doxil and DaunoXome (liposome-encapsulated doxorubicin and daunorubicin, respectively) exhibit negligible cardiotoxicity, presumably because of minimal cardiac exposure to the active drug with the pharmacokinetics of the liposome-encapsulated preparation.

Research

A broad consensus exists regarding the cardiotoxic effects of doxorubicin and its adverse effects on coQ10. Confirmatory evidence as to the extent to which introduction of exogenous coQ10 might mitigate such damage has developed more gradually.

Animal studies using rabbits found that mitochondrial degeneration is the most immediate and characteristic ultrastructural damage associated with the nonreversible cardiomyopathy induced by repeated exposure to doxorubicin.[58] All anthracyclines share cardiotoxicity to differing degrees, probably by the same mechanism. Using a rodent model, Shinozawa et al.[59] observed that among anthracyclines, aclarubicin had the smallest effect on rat liver microsomal lipid peroxidation, and the degree of this effect increased in the order of pirarubicin, doxorubicin, daunorubicin, and epirubicin.

Coenzyme Q10 demonstrated a protective effect against doxorubicin-induced damage to cardiac tissue in numerous animal experiments using mice, rats, and rabbits.[59-67] However, after confirming protective activity of coQ10 in conjunction with intraperitoneal administration of doxorubicin in mice, Schaeffer et al.[65] found that coQ10 failed to exhibit such a protective effect with intravenous anthracycline, as typical in clinical application with humans.

In reporting the findings of an experiment using a mouse model, Shinozawa et al.[68] observed that pretreatment with alpha-tocopherol significantly increased the tissue concentration of aglycone I (the major metabolite of doxorubicin) compared with saline placebo. They concluded that caution was required in the concomitant application of coQ10 and alpha-tocopherol with antitumor drugs, especially doxorubicin.[68] Some derivative literature has interpreted this statement as a contraindication of concomitant doxorubicin and coQ10 use. However, in two subsequent papers, these researchers noted that coadministration of coQ10 was associated with improved myocardial mitochondrial functions and "showed a significant decrease in mouse liver and heart microsomal lipid peroxidation" compared with doxorubicin-administered controls.[59,67]

In two studies (one in vitro and the other using rats) the addition of carnitine enhanced the protective effect of coQ10 in preventing anthracycline-induced cardiac damage.[69,70]

Iarussi et al.[71] demonstrated the protective effect of coQ on anthracycline-induced cardiotoxicity in a small study involving children being treated for acute lymphoblastic leukemia and non-Hodgkin's lymphoma.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Although further research with large, well-designed clinical trials is essential, coQ10 is already playing a role in many cancer treatment protocols employing multiple therapeutic modalities within an integrative clinical strategy. Administration of coQ10 before, during, and after chemotherapy with anthracyclines, particularly doxorubicin, is supported by scientific evidence and experienced clinicians; evidence of any interference by the nutrient on the therapeutic effect of the drug(s) is lacking and generally considered as unlikely. The usual dosage of coQ10 ranges from 50 to 100 mg orally twice daily and inherently requires close supervision and regular monitoring. Physicians and other health care professionals may consider reviewing the potential for such synergistic therapies with appropriate patients and provide referral information to centers specializing in such integrative approaches.

HMG-CoA Reductase Inhibitors (Statins)

Evidence: Atorvastatin (Lipitor), lovastatin (Altocor, Altoprev, Mevacor), combination drug: lovastatin and niacin (Advicor), pravastatin (Pravachol), simvastatin (Zocor); combination drug: simvastatin and extended-release nicotinic acid (Niaspan). Extrapolated, based on similar properties: Fluvastatin (Lescol, Lescol XL), rosuvastatin (Crestor).

Effect and Mechanism of Action

3-Hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) is normally converted to mevalonate, the substrate for biosynthesis of both cholesterol and coQ10. Coenzyme Q10 is a component of the LDL and VLDL fractions of cholesterol. Statin drugs exert their action in lowering cholesterol synthesis by competitively inhibiting hepatic synthesis of HMG-CoA reductase, the rate-limiting step of mevalonate synthesis, and thereby limiting conversion of HMG-CoA to mevalonate. Thus, HMG-CoA reductase inhibitors lower coQ10 (ubiquinone) levels, in a dose-dependent relationship, as they lower cholesterol.[72-79] Statins are the only class of lipid-lowering agents that are known to block the synthesis of mevalonate.

Research

Researchers have developed a consistent body of evidence over time demonstrating the adverse effects of HMG-CoA reductase inhibitors on the synthesis and function of coQ10 and determining the variables influencing this depletion pattern and its clinical significance. The emerging research demonstrating the central importance of coQ10 in myocardial and endothelial function underlies the growing concern for adverse effects on cardiovascular function, particularly among individuals who have developed or are susceptible to coronary artery disease and heart failure, especially within the context of aging and associated tendencies to coQ10 deficiency.[79-82] Significantly, Langsjoen and Langsjoen[69] have noted that all large clinical trials of statin therapy have excluded patients with "class III and IV heart failure such that long term safety of statins in patients with heart failure has not been established."

Beginning with Willis et al.[82a] in 1990, animal studies have evaluated the effects of statins on coQ blood and tissue levels. In addition to documenting the adverse effects of statin-induced depletion of coQ9 and coQ10 (species dependent) on ATP and creatinine phosphate in myocardium, these researchers also investigated prevention or reversal of resultant deficiency states through coadministration of exogenous

ubiquinone. Researchers further established that statins are the only class of lipid-lowering agents that directly impede the synthesis of mevalonate and therefore most directly interfere with coQ10 synthesis. Lipid-soluble statins (atorvastatin, cerivastatin, simvastatin, fluvastatin) showed more toxicity in this regard than water-soluble/hydrophilic statins (pravastatin).[83,84] In all animal studies where coQ10 was administered to the animals before initiation of statin therapy, the coQ10 blood and tissue depletion was completely prevented.

In 1990, Folkers et al.[72] first reported the interaction between statins and coQ10 in a small human trial that documented depletion of coQ10 by lovastatin and concluded that oral administration of coQ10 increased blood levels of coQ10 and was generally accompanied by an improvement in cardiac function. These researchers further suggested that coQ10 depletion might play a significant role in or be responsible for abnormal liver function and other adverse effects associated with statin use. Studies published in 1993 by Watts et al.[73] and Ghirlanda et al.[74] and later by De Pinieux et al.[75] (1996) confirmed the effects of HMG-CoA reductase inhibitors on blood levels of ubiquinone.

Nevertheless, some researchers have interpreted as clinically insignificant the degree of coQ10 depletion in some patient populations and questioned the need for compensatory coQ10 administration. In 1994, Laaksonen et al.[85] conducted inquiries into the effects of lovastatin and simvastatin on serum ubiquinone concentrations and found that after short-term lovastatin treatment, and after long-term simvastatin treatment, average serum ubiquinone levels were similar to those observed in a group of apparently healthy middle-aged men. However, in 1997, Mortensen et al.[76] conducted a randomized, double-blind clinical trial where serum levels of coQ10 were measured over a period of eighteen weeks in forty-five hypercholesterolemic individuals who had been prescribed the statin drugs lovastatin and pravastatin. A dose-related significant decline of the total serum level of coQ10 was found in both groups, with those taking lovastatin (20-80 mg/day) demonstrating the more pronounced decline. Likewise, Paloma'ki et al.[86] conducted a double-blind, placebo-controlled, crossover trial with 27 hypercholesterolemic men with coronary heart disease. During the 6-week treatment period using lovastatin (60 mg/day), ubiquinol content diminished by 13%, as measured by LDL phosphorus. However, in a later randomized, double-blind, placebo-controlled, crossover trial, Paloma'ki et al.[87] found that 180 mg coQ10 daily did not convincingly correct impaired defense against initiation of oxidation of LDL due to lovastatin treatment at 60 mg/day. They concluded that concomitant coQ10 only partially restored the drug-induced depletion of LDL ubiquinol and questioned the clinical benefits of coQ10 coadministration in individuals taking HMG-CoA reductase inhibitors, specifically lovastatin.

Bleske et al.[88] reported a lack of significant decline in measurable coQ10 in a randomized crossover study involving 12 healthy young normolipidemic volunteers treated with either pravastatin or atorvastatin for 4 weeks despite a significant decrease in LDL levels. Despite the short period involved and the dissimilarity between the test subjects and the typical patient population, these authors concluded: "Routine supplementation of CoQ10 may not be necessary when HMG-CoA reductase inhibitor therapy is administered." In contrast, Rundek et al.[89] conducted a prospective blinded study involving 34 subjects eligible for statin treatment according to standard criteria. After assessing baseline coQ10 status, investigators found that a decline in blood concentration of CoQ10 was already detectable after 14 days and had dropped by approximately 50% (mean, 1.26 μg/mL vs. 0.62 μg/mL) after 30 days. "Even brief exposure to atorvastatin causes a marked decrease in blood CoQ10 concentration," the authors observed, and further noted: "Widespread inhibition of CoQ10 synthesis could explain the most commonly reported adverse effects of statins, especially exercise intolerance, myalgia, and myoglobinuria." These researchers proposed that future research might benefit from measurement of tissue levels of cQ10 and concluded by suggesting that coadministration with coQ10 may be appropriate.[89]

Thus, coQ10 depletion appears to be well tolerated in younger and healthier patients, particularly in the short term, but the collected data demonstrate detrimental cardiac effects, especially with preexisting cardiac dysfunction, when subjected to this drug-induced depletion pattern. Some evidence indicates that pravastatin may reduce coQ10 levels to a lesser degree than other HMG-CoA reductase inhibitors.[74,76] Of particular concern to many clinicians and coQ10 investigators are the statin-induced changes in diastolic LV performance because myocardial diastolic function is highly ATP dependent and therefore particularly susceptible to coQ10 depletion. In November 2002, at the third conference of the International Coenzyme Q10 Association, Silver et al.[77] presented the results of a small pilot study involving six hyperlipidemic patients undergoing statin therapy. They reported that after 6 months of statin therapy, 67% demonstrated abnormalities of diastolic function.

The effect of statins on coQ10 is not paralleled by similar adverse impact on other antioxidant substances. Yoshida et al.[90] reported that LDL cholesterol (LDL-C) levels declined with low-dose simvastatin, with no attendant drop in the antioxidant levels of LDL or elevation of oxidative susceptibility of LDL. Subsequently, in a 3-month trial involving 42 hypercholesterolemic male patients treated with different doses of atorvastatin, simvastatin, and pravastatin, Passi et al.[78] observed not only the desired drop in total cholesterol and LDL-C, but also a significant dose-dependent plasma (and lymphocyte) depletion of $coQ10H_2$ and coQ10, although no accompanying change in the $coQ10H_2$/coQ10 ratio. Other antioxidants, both lipophilic (alpha- and gamma-tocopherol, lycopene, beta-carotene) and hydrophilic (vitamin C, uric acid) as well as glutathione, polyunsaturated fatty acid (PUFA), copper, and zinc–superoxide dismutase, were spared drug-induced depletion. Concomitant vitamin E may partially offset the loss of coQ10 caused by lovastatin.[91]

Following up on the early work of Folkers et al.,[72] human studies by Bargossi et al.[92] and Miyake et al.[93] found that coadministration of 90 to 100 mg daily of coQ10 protects against declining blood levels of coQ10 caused by statins without interfering with lipid-lowering activity. Pettit et al.[94] demonstrated reversal of statin toxicity to human lymphocytes in tissue culture. Significantly, in terms of clinical strategy, both coQ10 and statins appear to have a protective effect on endothelial function.[84,95-97] Wong et al.[98] found that concurrent coQ10 did not diminish the anti-inflammatory effect attributed to statins.

Brady et al.[99] and Goldman et al.[100] conducted surveys investigating the use of statins among general practitioners in the United Kingdom. They found that 80% believed that 80% of their patients had achieved target cholesterol levels (≤5 mmol/L). However, such outcomes were achieved in only 65% of patients initially, with that rate increasing to 78% after uptitrations and switching medication. Moreover, only 46% of patients demonstrated cholesterol reduction of 25% to the target levels, increasing to 56% after uptitrations or

switching medication. Notably, in response to such failure to achieve intended clinical outcomes, these practitioners stated that they would continue the unsuccessful therapy in 23.2% of such cases. These findings indicate that clinical guidelines are not being followed by many primary care physicians and that a significant gap exists between expectation and actual clinical results in statin prescribing. The issues of patient skepticism and compliance further complicate the realities of clinical application of statin therapy and reveal a significant departure from the scenarios envisioned in clinical trials and academic reviews.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Concomitant administration of coQ10 during statin therapy offers the opportunity to derive benefits from HMG-CoA reductase inhibitors while counteracting some of their more direct potential adverse effects and supporting broader clinical outcomes. Therapeutic dosages of coQ10 for cardiovascular conditions range from 50 mg daily to 100 mg or more three times daily. CoQ10 support is more important in elderly persons and those with a high susceptibility to or known history of cardiovascular disease, particularly heart failure. Genomic testing may be appropriate to elicit patterns of increased susceptibility to adverse effects of a particular statin drug or to impaired conversion of ubiquinone to ubiquinol. The need for coQ10 coadministration is dose dependent and should be initiated with statin therapy, if not earlier. Individuals prescribed statins that have a greater impact on coQ10, such as atorvastatin, may benefit from higher coQ10 dosage levels. A collaborative approach involving health care professionals trained and experienced in cardiology, nutrition, and other relevant modalities can provide optimal care for each individual through a customized and evolving program of integrative care. Thus, more broadly, strong emphasis needs to be placed on a comprehensive approach using proactive interventions that are safe and effective, such as regular exercise, stress reduction, healthy diet, omega-3 oils, L-carnitine, magnesium, L-taurine, and nutrient support emphasizing a network of antioxidant substances; consideration might also be given to potentially beneficial plant medicines, including *Crataegus* (hawthorn), garlic, and *Ginkgo biloba*.

It is noteworthy that, in apparent recognition of the significant adverse effects associated with statin-induced coQ10 depletion, two patents were awarded to Merck and Co. (now Merck, Sharp and Dohme) in 1990 for the combination of Mevacor in particular and statins in general with 1000 mg of coQ10. U.S. Patent No. 4,933,165 was issued for the following therapy: "A method of counteracting HMG-CoA reductase inhibitor-associated skeletal muscle myopathy in a subject in need of such treatment which comprises the adjunct administration of a therapeutically effective amount of HMG-CoA reductase inhibitor and an effective amount of Coenzyme Q10 to counteract said myopathy."[101] Merck is also the assignee for U.S. Patent No. 4,929,437, which applies to a pharmaceutical composition and method of counteracting elevated transaminase levels associated with HMG-CoA reductase inhibitor. The method described comprises the adjunct administration of an effective amount of a statin inhibitor and an effective amount of coQ10.[102] These actions indicate that Merck was convinced of the clinical value and market potential of administering coQ10 in conjunction with statins, at least enough to apply for and receive patents for that combination of therapies. Merck's patents would preclude other companies from combining coQ10 with other statins in a single-dose form. It is not clear why Merck thus far has chosen not to market such a combination with Mevacor (lovastatin).

Sulfonylureas and Related Oral Hypoglycemic Agents

Evidence: Acetohexamide (Dymelor), glyburide (glibenclamide; Diabeta, Glynase Prestab, Glynase, Micronase, Pres Tab), phenformin (Debeone, Fenformin), tolazamide (Tolinase)

Related but evidence lacking for extrapolation: Glimepiride (Amaryl), metformin (Dianben, Glucophage, Glucophage XR); combination drugs: glipizide and metformin (Metaglip); glyburide and metformin (Glucovance).

Similar properties but evidence indicating no or reduced interaction effects: Chlorpropamide (Diabinese), glipizide (Glucotrol, Glucotrol XL), tolbutamide (Orinase, Tol-Tab).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

◇≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**

≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Certain hypoglycemic drugs inhibit the coQ10 enzyme NADH-oxidase.

Research

Numerous studies have reported that coQ10 levels tend to be lower in individuals with type 2 diabetes mellitus than in the general population. For example, comparing the activity of succinate dehydrogenase–coQ10 reductase in leukocytes from blood samples, Kishi et al.[103] found that the mean percent deficiency of coQ10 was significantly greater (20% ± 0.7%) in 120 patients with diabetes than in healthy controls (16% ± 1.0%). Likewise, a mean percentage deficiency of approximately 20% was observed in 37 individuals whose condition was being treated by diet alone.

Kishi et al.[103] reported that acetohexamide, glyburide, phenformin, and tolazamide inhibit NADH-oxidase in vitro; however, tolbutamide, glipizide, and chlorpropamide had no inhibitory effect on NADH-oxidase or succinoxidase. In assessing patients under treatment, they further found that coQ10 deficiency was greater in individuals taking phenformin and tolazamide than in controls. Based on these observations, an even greater depletion pattern would theoretically occur in individuals administered acetohexamide and glyburide because they exert more potent inhibitory activity on coQ10 enzymes. Overall, the evidence thus far available suggests that the added effect of oral hypoglycemic agents on compromised coQ10 levels often characteristic of individuals with diabetes mellitus might exert a further adverse effect on bioenergetics, ATP generation, and insulin biosynthesis.

Concern has been raised that coadministration of coQ10 might destabilize patients under treatment for diabetes. In a randomized, double-blind trial involving hypertensive patients with coronary artery disease, Singh et al.[104] found that coadministration of 60 mg coQ10 twice daily in 30 of 59 total patients was associated with a significant decline in fasting and 2-hour plasma insulin and glucose levels, compared with controls receiving a B-vitamin complex. These researchers interpreted their findings as suggesting that "treatment with

coenzyme Q10 decreases blood pressure possibly by decreasing oxidative stress and insulin response in patients with known hypertension receiving conventional antihypertensive drugs.[**] Subsequently, in a randomized, double-blind, placebo-controlled, 2 × 2 factorial intervention involving 74 subjects with uncomplicated type 2 diabetes and dyslipidemia, Hodgson et al.[105] found that subjects who received 100 mg coQ orally twice daily (200 mg/day), with 200 mg fenofibrate each morning, for 12 weeks demonstrated a threefold increase in plasma coQ concentration and improved blood pressure and long-term glycemic control. Although not associated with reduced oxidative stress (assessed by plasma F2-isoprostane levels), as hypothesized, the primary effects attributable to coQ10 were significant decreases in systolic and diastolic blood pressure and hemoglobin A_{1c}.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Health care professionals treating individuals with diabetes and especially those being prescribed oral hypoglycemic agents, particularly acetohexamide and glyburide, are advised to consider coadministration of coenzyme Q10 (30-100 mg twice daily) as adjunctive therapy for the primary condition (and typical comorbid conditions) and to mitigate adverse effects of the medications. Close supervision and regular monitoring of glucose levels and blood pressure are warranted, especially while introducing coQ10 or changing dietary programs or dosage levels of any relevant medication. After a period of stabilization, gradual, staged reduction in dosage of oral hypoglycemic agents may be possible and appropriate with continued coadministration of coQ10. Attending health care providers are also encouraged to advise patients to be watchful for changes indicative of unstable blood glucose levels, especially acute fatigue, malaise, difficulty focusing, agitation, irritability, lethargy, cravings for sweets, and other characteristics of hypoglycemia.

Tricyclic Antidepressants (TCAs)

Evidence: Amitriptyline (Elavil).
Extrapolated, based on similar properties: Amitriptyline combination drug: amitriptyline and perphenazine (Etrafon, Triavil, Triptazine); amoxapine (Asendin), clomipramine (Anafranil), desipramine (Norpramin, Pertofrane), doxepin (Adapin, Sinequan), imipramine (Janimine, Tofranil), nortriptyline (Aventyl, Pamelor), protriptyline (Vivactil), trimipramine (Surmontil).

Interaction Type and Significance

◈≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**
≈≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, Not Requiring Professional Management**
☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **3. Possible**
Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Tricyclic antidepressants (TCAs) are antagonistic to coenzyme Q10 enzymes NADH-oxidase and succinoxidase.[49] Furthermore, these agents are class I antiarrhythmics.[106] Drug-induced coQ10 deficiency may be a contributing factor to the cardiac adverse effects associated with TCAs.

Research

Tricyclic antidepressant drugs, including amitriptyline, particularly when given in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolonged conduction time.[49] TCAs inhibit NADH-oxidase and succinoxidase in vitro.[52] Myocardial infarction and stroke have also been reported with TCAs.[107,108] At this time, direct evidence of the frequency, circumstances, and severity of this interaction from large-scale, randomized human trials is lacking. However, the pharmacological principles of this interference/depletion pattern is widely accepted, particularly inhibition of myocardial respiration by psychotherapeutic drugs and its prevention by coQ10, as is restoration of healthy coQ10 levels through oral administration.[52]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Coadministration of coQ10 may prevent myocardial depression and other adverse effects on cardiac function associated with use of TCAs. Physicians prescribing TCAs are advised to discuss these risks and the potential benefits of concomitant coQ10 with their patients. CoQ10, 20 to 100 mg three times daily, can offset depletion resulting from TCA use and may reduce adverse effects and attendant cardiac risks.

Warfarin and Related Oral Vitamin K Antagonist Anticoagulants

Warfarin (Coumadin, Marevan, Warfilone).
Similar properties but evidence lacking for extrapolation: Anisindione (Miradon), dicumarol, ethyl biscoumacetate (Tromexan), nicoumalone (acenocoumarol; Acitrom, Sintrom), phenindione (Dindevan), phenprocoumon (Jarsin, Marcumar).

Interaction Type and Significance

? **Interaction Possible but Uncertain Occurrence and Unclear Implications**
✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**
✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

Probability: **5. Improbable**
Evidence Base: ▽ **Mixed** or ☐ **Inadequate**

Effect and Mechanism of Action

Warfarin exerts its therapeutic effect by interfering with vitamin K metabolism. As quinones, coenzyme Q10 and various forms of vitamin K share a chemical structure. As a result of this vague structural similarity, coQ10 could theoretically interfere with the action of warfarin.[109,110]

Research and Reports

Although often presented as well documented and almost self-evident in derivative literature, the evidence supporting this proposed interaction is at best suggestive and fragmentary. The available data are lacking in substantive information necessary to predict the character and severity of any such adverse event. Furthermore, the frequency of alleged incidence is far below what would be predicted based on known usage patterns.

The medical literature contains at least four case reports describing decreased international normalized ratios (INRs) subsequent to the introduction of coQ10 in patients previously stabilized on warfarin therapy. When the individuals stopped taking the coQ10, their previous responsiveness to warfarin

resumed.[111,112] Heck et al.[113] (2000) published a cautionary review of this potential interaction based on these available case reports.

Engelsen et al.[113a] conducted a small, randomized, double-blind, placebo-controlled, crossover trial in which patients stabilized on long-term warfarin therapy were administered coQ10. Concomitant use of warfarin and coQ10 did not significantly alter the warfarin dosage needed to maintain an INR in the acceptable range of 2.0 to 4.0 in these patients.

Emerging knowledge of the significant pharmacogenomic variability that influences warfarin activity, sensitivity, and resistance suggests that such possible interactions may occur only in patients with certain genotypes and that inconsistencies in the literature may reflect such variability.[114]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The clinical significance and frequency of occurrence of this interaction are uncertain, even though the theoretical foundation for this interaction is plausible and several case reports have appeared. Grounds for concern are amplified because of the high probability of overlap among the patient populations interested in coQ10 for cerebrovascular benefits and those being treated for the disorders for which warfarin is often prescribed. Physicians prescribing of warfarin should be aware of the possible risk of treatment effect alteration when coQ10 is coadministered and closely monitor any such patients for reduced effects. INR levels and prothrombin time (PT) should be checked with greater frequency during the first 2 weeks after either starting or stopping coQ10 to verify that the risk of bleeding or clotting (as reflected by INR value) is not being affected by the coQ10 doses. In general, it is important always to monitor PT twice weekly when medications, supplements, and diet are changed in any significant way; this is the safest and most reliable method of compensating for unexpected or idiosyncratic interactions in patients undergoing treatment with coumarin derivatives.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Fenofibrate, Gemfibrozil, and Related Fibrates

Bezafibrate (Bezalip), ciprofibrate (Modalim), clofibrate (Atromid-S), fenofibrate (Tricor, Triglide, Lofibra), gemfibrozil (Apo-Gemfibrozil, Lopid, Novo-Gemfibrozil).

No mechanism of action has been articulated for the phenomena reported in the available research, nor has available evidence indicated a consistent effect. It is generally accepted that the mechanism of action of fibrates in lowering cholesterol does not involve direct inhibition of mevalonate, the substrate for biosynthesis of both coenzyme Q10 and cholesterol.[73]

The evidence for this interaction is in preliminary stages, and understanding of its clinical implications is. In a randomized, placebo-controlled, crossover study involving 21 men with combined hyperlipidemia, Aberg et al.[115] found that 10 to 12 weeks of gemfibrozil treatment reduced serum coQ10 levels by more than 40%; alpha- and gamma-tocopherol as well as serum antioxidant levels also dropped. Also, normolipemic control subjects had significantly lower levels of ubiquinone and other antioxidants than placebo-treated patients, as part of an association between antioxidants and lipoprotein lipids. The authors concluded that the mechanisms and clinical significance of this finding were "unclear." In contrast, in a randomized, double-blind, placebo-controlled, 2 × 2 factorial intervention involving 74 subjects with uncomplicated type 2 diabetes and dyslipidemias, Hodgson et al.[105] found that subjects who received 100 mg coQ10 orally twice daily (200 mg/day), with 200 mg fenofibrate each morning, for 12 weeks demonstrated a threefold increase in plasma coQ concentration and improved blood pressure and long-term glycemic control. Although not associated with reduced oxidative stress, as hypothesized, the primary effects attributable to coQ10 were significant decreases in systolic and diastolic blood pressure and hemoglobin A_{1c}. The specific influence of fenofibrate on coQ10 levels and outcome measures was not determined.

Another factor involving the impact of fibrate derivatives on coQ10 derives from their use in combination with statin drugs (HMG-CoA reductase inhibitors). Gemfibrozil, in particular, inhibits the glucuronidation of most statins (especially cerivastatin), thereby increasing their levels and the attendant risks, including interference with coQ10 synthesis and function. Fluvastatin appears to be the only statin with which gemfibrozil does not increase drug levels.

The evidence for a direct interaction between fibrates and coQ10 remains unclear and lacking direct investigation. Nevertheless, such preliminary status does not contradict the therapeutic value of coQ10 (e.g., 30-100 mg twice daily) in individuals with or at significant risk for cardiovascular conditions, particularly heart disease. Concomitant administration of fibrates and coQ10 may be medically appropriate as a preventive measure or a treatment intervention for many such individuals. Health care providers are advised to discuss such integrative approaches with patients as part of a comprehensive review of options toward a personalized and evolving therapeutic strategy.

Hydrochlorothiazide and Related Thiazide Diuretics

Hydrochlorothiazide (Aquazide, Esidrix, Ezide, Hydrocot, HydroDiuril, Microzide, Oretic).

Related: Bendroflumethiazide (bendrofluazide; Naturetin); combination drug: bendrofluazide and propranolol (Inderex); benzthiazide (Exna), chlorothiazide (Diuril), chlorthalidone (Hygroton), cyclopenthiazide (Navidrex); combination drug: cyclopenthiazide and oxprenolol hydrochloride (Trasidrex); hydrochlorothiazide combination drugs: hydrochlorothiazide and amiloride (Moduretic); hydrochlorothiazide and captopril (Acezide, Capto-Co, Captozide, Co-Zidocapt); hydrochlorothiazide and enalapril (Vaseretic); hydrochlorothiazide and lisinopril (Prinzide, Zestoretic); hydrochlorothiazide and losartan (Hyzaar); hydrochlorothiazide and metoprolol (Lopressor HCT); hydrochlorothiazide and spironolactone (Aldactazide); hydrochlorothiazide and triamterene (Dyazide, Maxzide); hydroflumethiazide (Diucardin), methyclothiazide (Enduron), metolazone (Zaroxolyn, Mykrox), polythiazide (Renese), quinethazone (Hydromox), trichlormethiazide (Naqua).

Hydrochlorothiazide exerts a mild to moderate inhibitory effect on NADH-oxidase.[47] Although preliminary indications suggest that a probable adverse effect of thiazide diuretics on coQ10 status, this interaction has not been investigated adequately to provide evidence sufficient to enable a well-founded assessment of its frequency, circumstances, severity, or clinical significance. Nevertheless, patients with chronic heart failure are consistently deficient in coQ10, typically proportionate to the severity of the cardiac dysfunction, and will generally benefit from coQ10 as part of a comprehensive therapeutic strategy.[46] No evidence is available to suggest that such nutritional support would interfere with the clinical effectiveness of diuretic therapy.

Levothyroxine and Related Thyroid Hormones

L-Triiodothyronine (T_3): Cytomel, liothyronine sodium, liothyronine sodium (synthetic T_3), Triostat (injection).
Levothyroxine (T_4): Eltroxin, Levo-T, Levothroid, levothyroxine (synthetic), levoxin, Levoxyl, Synthroid, thyroxine, Unithroid.
L-Thyroxine and L-triiodothyronine ($T_4 + T_3$): animal levothyroxine/liothyronine, Armour Thyroid, desiccated thyroid, Westhroid.
L-Thyroxine and L-triiodothyronine (synthetic $T_4 + T_3$): Euthroid, Euthyral, liotrix, Thyar, Thyrolar.
Dextrothyroxine (Choloxin).

The physiological interrelationship between coenzyme Q10 and thyroid function is multifaceted and has been investigated in many contexts. In the literature, plasma coQ10 determination has been discussed as a potentially useful diagnostic tool in differential diagnosis of thyroid diseases. Kotake et al.[116] observed protective effect of exogenously administered coQ10 on thyrotoxic heart in rabbits. Mancini et al.[117] demonstrated that coQ10 levels have a significant inverse correlation with thyroid hormone concentration in patients with spontaneous hyperthyroidism or hypothyroidism. Furthermore, exogenous administration of coQ10 may be beneficial in hyperthyroid patients with risk factors for heart failure.

Given these and other known patterns of mutual influence between coQ10 and thyroid hormone, oral coQ10 theoretically may affect thyroid hormone levels and alter the effects of levothyroxine or other thyroid medications. Evidence of any such direct interaction of clinically significance is lacking. Nevertheless, physicians or other health care professionals recommending coQ10 to individuals taking thyroid medication are advised to monitor such patients regularly. Clinical investigation of potential interactions, their character, and clinical implications is warranted.

Orlistat

Orlistat (alli, Xenical).

Depletion of coenzyme Q10 in individuals using orlistat has been suggested, but findings from clinical trials or other direct substantive evidence is lacking. Nevertheless, physicians prescribing orlistat as part of a comprehensive program for reducing obesity, hypercholesterolemia, or other cardiovascular risk factors are advised to consider and discuss with patients the potential benefits of 30 to 50 mg twice daily (or more) of coQ10. Further research is warranted to determine if the action of orlistat in interfering with fat digestion and assimilation might produce a substantial adverse effect on coQ10 synthesis and metabolism.

Pentoxifylline

Pentoxifylline (Pentoxil, Trental).

Portakal and Inal-Erden[118] reported that combined pentoxifylline and coQ10 pretreatment reduced ischemia-reperfusion damage in the rat liver, as indicated by hepatic glutathione and malondialdehyde levels. Treatment with pentoxifylline alone did not produce beneficial results.

Radiotherapy

Radiotherapy

Lund et al.[119] reported a reduced effect of radiation therapy on small cell lung cancer (SCLC) with concomitant coQ10 using a human SCLC xenograft into an immunodeficient nude mouse model. They observed interference with radiation therapeutic effect at 40 mg/kg coQ, but not at 10 mg/kg. The 10-mg/kg dosage would be 600 to 800 mg coQ10 in average-sized patients, which is a frequently used dose range in integrative care of cancer patients. The 40-mg/kg dosage is equivalent to 2.8 g for a 70-kg person, a dose infrequently, if ever, used in nutritional oncology.

Zidovudine (AZT) and Antiretroviral Agents, Reverse-Transcriptase Inhibitor (Nucleoside)

Evidence: Zidovudine (azidothymidine, AZT, ZDV, zidothymidine; Retrovir); combination drugs: zidovudine and lamivudine (Combivir); abacavir, lamivudine and zidovudine (Trizivir).
Extrapolated, based on similar properties: Abacavir (Ziagen), didanosine (ddI, dideoxyinosine; Videx), dideoxycytidine (ddC, zalcitabine; Hivid), lamivudine (3TC, Epivir), stavudine (D4T, Zerit), tenofovir (Viread).

Zidovudine (AZT/ZDV) has been associated with "ragged-red" fiber myopathy because of its effects on myocyte mitochondria; this condition typically is reversible with cessation of the drug. Rosenfeldt et al.[120] reported the case of a 52-year-old male who first developed ragged-red fiber myopathy in 1985 while on effective ZDV-based combination antiretroviral therapy (ART), 14 years after diagnosis of HIV infection. The patient demonstrated "an excellent recovery" after administration of coQ10, known for its antioxidant activity in mitochondria, and was able to continue ART without disruption. The authors concluded that this response to coQ10 therapy "suggests a novel therapy for further investigation targeted at ZDV induced myopathy, potentially allowing continuation of antiviral treatments including ZDV."

NUTRIENT-NUTRIENT INTERACTIONS

L-Carnitine

Concomitant administration of coenzyme Q10 and L-carnitine may result in an additive effect.[69,70] Such a potential interaction likely would be beneficial, but direct evidence from human trials is lacking. Close supervision and regular monitoring are warranted at the initiation of and through the course of any such coadministration, particularly in individuals with serious heart disease or other cardiovascular conditions. Clinical investigation of potential interactions, their character, and clinical implications is warranted.

Vitamin B_6, Pyridoxine, Pyridoxal 5'-Phosphate

Pyridoxal 5'-phosphate is required in the conversion of tyrosine to 4-hydroxyphenylpyruvic acid; the formation of the quinone nucleus being the first step in coQ10 biosynthesis. Many researchers have noted the parallel decline in coQ10 and B_6 levels associated with aging. In a pilot study involving 29 patients and healthy volunteers, Willis et al.[121] observed strong positive correlations between blood levels of coQ10 and the specific activity of erythrocyte glutamine-oxaloacetic acid transaminase (EGOT) and between coQ10 and the percent saturation of EGOT with pyridoxal phosphate (PLP).[121] Further research is warranted to better understand this physiological relationship and the potential for synergistic therapeutics using nutritional interventions.

Vitamin E, Alpha-Tocopherol

Vitamin E and coQ10 function in complementary roles within physiological antioxidant networks as the principal fat-soluble antioxidants in membranes and lipoproteins. In particular,

$coQH_2$, the reduced form of coQ, is capable of regenerating alpha-tocopherol. Alpha-tocopherol becomes oxidized whenever it neutralizes a free radical, such as a lipid hydroperoxyl radical, and consequently an alpha-tocopheroxyl radical appears. Subsequently, when $coQH_2$ reacts with the alpha-tocopheroxyl radical, alpha-tocopherol is regenerated and $CoQH$, the semiquinone radical, is produced. Thus, the formation of oxidized lipids and the consumption of alpha-tocopherol are suppressed while $CoQH_2$ is present.[122,123]

Some researchers have reported that vitamin E may reduce blood levels of coQ10. Coadministration of vitamin E and coQ10 would reasonably be predicted to have a mutually supportive effect, which would also enhance the broader activity of the physiological antioxidant network against oxidative stress. Further investigation into the physiological functions and therapeutic roles of vitamin E, coQ10, and other antioxidants is underway within both research and clinical settings and promises to deepen our understanding of their roles in physiology, health enhancement, and treatment of disease.

HERB-NUTRIENT INTERACTIONS

Ginkgo

Ginkgo *(Ginkgo biloba)*.

In an open, pilot study, Lister[124] reported significant improvements in the quality-of-life self-rating scores of 64% of individuals with clinically diagnosed fibromyalgia syndrome after administration of 200 mg coQ10 and 200 mg *Ginkgo biloba* extract daily for 84 days. Controlled clinical trials involving larger number of subjects with a placebo group are warranted to further investigate this potential therapeutic synergy and assess its clinical implications, particularly in treating individuals with mitochondrial dysfunction.

The 126 citations for this monograph, as well as additional reference literature, are located under Coenzyme Q10 on the CD at the back of the book.

DHEA

Nutrient Name: DHEA (dehydroepiandrosterone).
Synonym: Prasterone.
Related Compound: Dehydroepiandrosterone sulfate (DHEA-S); 3-acetyl-7-oxo DHEA (7-keto DHEA).

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Alprazolam, triazolam Benzodiazepines ✗✗/◈◈	Alprazolam has been observed to elevate circulating DHEA (while decreasing ACTH and cortisol). DHEA may reduce hepatic metabolism of these benzodiazepines by inhibiting CYP4A and CYP3A23, potentially raising levels. Clinical significance of this potential interaction is unclear, and supporting evidence is preliminary.	Coadministration does not appear to be contraindicated if otherwise appropriate. Drug levels and AUC may be increased. Supervise and monitor.
Amlodipine ⊕	Amlodipine increases serum DHEA-S and androstenedione levels (and decreases cortisol) in some individuals. This action may contribute to beneficial effect on glucose tolerance, insulin sensitivity, and cardiovascular risk.	Coadministration may be beneficial. Supervise and monitor.
Anticoagulant medications ✗/⊕✗	Evidence concerning this possible interaction is mixed and insufficient to determine any consistent pattern or assess clinical significance. Speculation of potential for increased clotting from DHEA is not substantiated by available evidence.	Coadministration does not appear to be contraindicated if otherwise appropriate. Supervise and monitor.
Anticonvulsant medications Carbamazepine, phenytoin ✗✗✗	Some antiepileptic drugs may decrease levels of DHEA and DHEA-S by inducing P450 enzymes, particularly CYP3A4. Exogenous DHEA may interfere with action of anticonvulsants and could theoretically increase risk of aggressive behavior by elevating androgen levels. mechanisms of possible interactions are as yet unclear, and substantive evidence is lacking regarding their clinical significance. Limited case reports of marginal quality suggest need for caution or avoidance.	Caution indicated and concurrent use contraindicated unless otherwise appropriate. Supervise and monitor.
Clonidine, fluoxetine ⊕⊕	DHEA may enhance activity of clonidine and fluoxetine by restoring response of beta-endorphin. Preliminary evidence suggests reasonable probability of clinically significant supportive interaction.	Coadministration may be beneficial unless otherwise contraindicated. Supervise and monitor.
Corticosteroids, oral ≈≈/⊕⊕	Corticosteroids can lower serum levels of DHEA and DHEA-S, as well as ACTH and other key hormones within interdependent regulatory systems. DHEA may enhance activity of prednisolone and counteract some adverse effects associated with long-term steroid therapy.	Coadministration may be protective and/or therapeutic with long-term steroid use, especially if otherwise indicated. Supervise and monitor.
Estrogens/progestins Hormone replacement therapy (HRT) Oral contraceptives (OCs) ✗✗/⊕✗/⊕	DHEA and estrogen play mutually supportive roles, which may be enhanced with exogenous administration of either or both substances and their precursors. Although reasonably grounded and supported by clinical experience and anecdotal reports, evidence supporting interaction is primarily suggestive, and understanding of its clinical significance preliminary and evolving.	Coadministration may be beneficial unless otherwise contraindicated. Supervise and monitor.
Methyltestosterone Androgens ⊕⊕/⊕✗/✗✗	DHEA can be converted into testosterone, and administration of exogenous DHEA, alone or with methyltestosterone (or testosterone), can increase testosterone levels. Coadministration may enhance therapeutic efforts to increase androgen levels. Mechanism clear and axiomatic, but clinical significance as yet uncertain and therapeutic guidelines evolving.	Coadministration may be beneficial unless otherwise contraindicated. Supervise and monitor.
Zidovudine (AZT) Reverse-transcriptase inhibitor (nucleoside) antiretroviral agents ⊕⊕	DHEA levels tend to be low in HIV-infected individuals, and depression is common with this patient population. DHEA can enhance levels of testosterone, estradiol, insulin-like growth factor, and growth hormone, all of which can be associated with depression and debilitation. DHEA may also modulate inflammatory cytokines such as tumor necrosis factor. Coadministration of DHEA to HIV patients with nonmajor depression on antiretroviral regimens can significantly improve their psychological state.	Coadministration may be beneficial unless otherwise contraindicated. Supervise and monitor.

ACTH, adrenocorticotropic hormone; *CYP*, cytochrome P450; *AUC*, area under the curve; *HIV*, human immunodeficiency virus.

NUTRIENT DESCRIPTION

Chemistry and Forms

Dehydroepiandrosterone; dehydroepiandrosterone sulfate.

Physiology and Function

Dehydroepiandrosterone (DHEA) and its sulfate ester metabolite (DHEA-S) are among the most abundant steroids in the human body, yet their physiological roles remain largely unknown. DHEA is a naturally occurring steroid synthesized in the adrenal cortex, gonads, central nervous system (CNS), skin, and gastrointestinal (GI) tract and is a precursor for the synthesis of more than 50 hormones, including androgenic and estrogenic steroids.

Adrenal production and serum concentrations of DHEA are known to peak between ages 25 and 30 years and thereafter decrease with age, severe illness, and chronic stress. The main characteristic of DHEA is that its concentration in plasma varies throughout life, being low during early childhood and after age 60. Aging in humans is accompanied by a progressive decline in the secretion of DHEA and DHEA sulfate (DHEA-S), paralleling that of the growth hormone–insulin-like growth factor-I (GH-IGF-I) axis. Although the functional relationship of the

decline of the GH-IGF-I system and catabolism is recognized, the biological role of DHEA in human aging remains undefined. DHEA has different effects in men, premenopausal women, and postmenopausal women, with associations often reversed for older men and women. DHEA and DHEA-S are metabolized by the hepatic cytochrome P450 (CYP450) enzyme system or via a cutaneous pathway, where it is metabolized by the skin and other tissues sensitive to sex steroids.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Low endogenous levels of DHEA and DHEA-S have consistently been associated with the aging process and diseases such as systemic lupus erythematosus (SLE), diabetes, and cancer. Consequently, DHEA administration has primarily been suggested to prevent or reverse such conditions. For example, by modulating endocrine parameters and synthesis of neuroactive steroids, low-dose DHEA (25 mg/day) administration increases adrenal hormone plasma levels in early and late menopause.[1] Likewise, DHEA monotherapy can be effective for midlife-onset major and minor depression.[2] However, Nair et al.[3] found that administration of DHEA in elderly subjects does not demonstrate "physiologically relevant beneficial effects" on markers for antiaging, such as body composition, physical performance, insulin sensitivity, or quality of life, although they did observe an increase in plasma levels of sulfated DHEA. The role of DHEA within hormone replacement therapy (HRT) and as an antiaging substance remains controversial and research preliminary.

Historical/Ethnomedicine Precedent

Antiaging and longevity tonic medications have been sought-after, proposed, and used throughout history worldwide in almost all civilizations. Such medications have often been associated with human reproductive function, hormones, and fluids. Needham discussed the use of crystallized medications derived from the collected urine of adolescents in ancient China. Early in the twentieth century, the adrenal glands came into focus with the research work of experimental physiologist Walter Cannon at the University of Chicago and his pioneering study of homeostasis and the autonomic nervous system. Clinical application of these concepts began with the work of Henry Harrower, Royal Lee, and others with the use of glandular preparations in therapeutic nutrition.

Possible Uses

Addison's disease, adrenal insufficiency, allergic disorders, Alzheimer's disease, andropause, anorexia nervosa, atherosclerosis, athletic performance enhancement, autoimmune diseases, cancer prevention, chronic fatigue syndrome, dementia, depression, diabetes mellitus (type 2), endothelial function, erectile dysfunction, fatigue, human immunodeficiency virus and acquired immunodeficiency syndrome (HIV/AIDS) support, hypercholesterolemia, hypogonadism, immune modulation, insulin sensitivity, longevity, menopause, multi-infarct dementia, multiple sclerosis, obesity, osteoporosis, Parkinson's disease, rheumatoid arthritis, Sjögren's syndrome, systemic lupus erythematosus (SLE), testosterone deficiency.

Dietary Sources

Animal proteins are the richest dietary sources of DHEA.

Nutrient Preparations Available

A semisynthetic form of DHEA is available as a nutraceutical. Some product surveys have found variable potency and quality in commercially available DHEA preparations.

Dosage Forms Available

Capsule, liquid, tablet, and sublingual form.

Source Materials for Nutrient Preparations

Soy or wild yams are used for extraction of a steroid precursor molecule, which is then chemically synthesized into DHEA (and a wide variety of other sex hormones).

Dosage Range

Adult

Dietary:

Average American daily intake: DHEA per se is not a normal dietary component.

Recommended dietary allowance (RDA): No RDA has been established.

Supplemental/Maintenance: Usually not necessary. Optimal levels of intake have not been established. Individuals who have not been diagnosed as having a hormonal deficiency pattern, preferably through laboratory tests, should usually not take DHEA.

Pharmacological/Therapeutic: There is no consensus among practitioners who prescribe DHEA as to an optimal dose. Some practitioners are routinely prescribing 10 to 30 mg per day for healthy men and 5 to 15 mg per day for healthy women, whereas others often prescribe 50 to 100 mg per day. Dosage is usually split into morning and late-afternoon doses. Much larger doses have been administered under close observation to patients with cancer, acquired immunodeficiency syndrome (AIDS), SLE, and other serious conditions. The metabolic fate of exogenous DHEA is variable and unpredictable because it can become one of many other hormones. Orally administered DHEA can also be metabolized by enzymes in the small intestine, causing biotransformation even before it has been absorbed. Even when using laboratory testing to evaluate appropriateness of and response to DHEA, no data yet exist on what constitutes a physiologic dose or an optimum serum level. Consequently, the judicious practice would be to err on the side of caution by using initial low doses of DHEA, following a conservative schedule for any dosage increase, and observing discrimination and vigilance in the use of supraphysiologic doses.

Beyond those who prescribe DHEA, its use is a controversial, but generally unexplored, issue. Opinions vary widely as to the benefits and risks of using hormones such as DHEA as nutraceutical therapies. Any such application should be monitored by a health care professional trained and experienced in nutritional therapeutics and is best undertaken after initially testing DHEA levels.

Toxic: No toxic dose has been established.

Pediatric (< 18 years)

DHEA is generally not considered therapeutically appropriate in children or adolescents, in the absence of conditions such as Addison's disease, and has not been well studied in such populations.

SAFETY PROFILE

Overview

The long-term safety of DHEA administration has not been established through well-done clinical studies involving human subjects from a variety of populations. The inherent tendency of DHEA to increase or otherwise alter healthy physiologic levels of a wide range of hormones suggests that unintended effects are highly probable and potentially adverse for some individuals in the absence of experienced clinical management.

Nutrient Adverse Effects

General Adverse Effects

Adults. Masculinization in women; altered secondary sexual characteristics in either gender.

Mutagenicity. Preliminary evidence and extrapolated hypotheses have been presented on both increased and decreased risk of angiogenesis and cancer in relation to endogenous and exogenous DHEA.

Adverse Effects Among Specific Populations

DHEA is often prescribed for biological aging, functional symptoms of aging, and prevention of functional degeneration hypothesized to derive from age-related depletion in hormonal levels. Given that the use of prescription medications increases with age, issues of potential interactions, adverse or beneficial, deserve special attention among the elderly population.

Pregnancy and Nursing

The safety of DHEA use during pregnancy and lactation has not been established, and such application is contraindicated because of potential impact on hormonal levels, regulatory systems, and fetal development.

Infants and Children

DHEA administration is generally contraindicated in children and adolescents because theoretically it may interfere with normal hormonal regulatory systems and developmental processes.

Contraindications

Given DHEA's potential effect on testosterone and estrogen levels, its use by individuals with personal or family history of prostate or breast cancer, or other hormonally mediated cancer, is contraindicated. Such recommendation is based more on caution and plausibility than on a consistent or well-developed body of evidence. The 7-keto variant of DHEA was developed to circumvent the metabolic pathways associated with such hormonally mediated adverse effects.

Testing

Serum or saliva. Monitoring free and sulfate levels is considered the most accurate method of tracking DHEA levels, but exogenous DHEA can become many other hormones. Orally administered DHEA can also be metabolized by enzymes in the small intestine, causing biotransformation even before it has been absorbed.

INTERACTIONS REVIEW

Strategic Considerations

DHEA is often prescribed for biological aging, functional symptoms of aging, and prevention of functional degeneration hypothesized to derive from age-related depletion in hormonal levels. Because use of prescription drugs increases with age, issues of potential interactions, adverse or beneficial, deserve special attention in elderly individuals.

The status of endogenous DHEA and DHEA-S constitutes a significant aspect of many health conditions, especially those associated with aging. A wide range of medications may significantly increase or decrease circulating concentrations of DHEA and DHEA-S by various mechanisms. Some drugs may affect the hypothalamic-pituitary axis by inhibiting adrenocorticotropic hormone (ACTH) and therefore lower DHEA and DHEA-S levels. Other medications induce CYP450 enzymes, hasten metabolism of DHEA and DHEA-S, and decrease circulating concentrations of the hormones. The ratio of DHEA and DHEA-S can also be altered by agents that affect sulfatase activity. Whether a disease state is associated with lower levels of endogenous DHEA and DHEA-S or a medication alters such concentrations, minimal clinical evidence exists to indicate whether oral administration is safe or effective, or problematic and contraindicated, in specific patient populations.

Whenever DHEA is being prescribed for primary therapeutic effect or to counter a potential endogenous deficiency or drug-induced depletion, close supervision and regular monitoring are important, as is coordination of pharmacological interventions within an integrative perspective.

NUTRIENT-DRUG INTERACTIONS

Alprazolam, Triazolam, and Related Benzodiazepines

Evidence: Alprazolam (Xanax), triazolam (Halcion).
Extrapolated, based on similar properties: Bromazepam (Lexotan), chlordiazepoxide (Librium), clonazepam (Klonopin, Rivotril), clorazepate (Gen-Xene, Tranxene), diazepam (Valium), estazolam (ProSom), flurazepam (Dalmane), lorazepam (Ativan), medazepam (Nobrium), midazolam (Hypnovel, Versed), oxazepam (Serax), prazepam (Centrax), quazepam (Doral), temazepam (Restoril).

Interaction Type and Significance

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

◇◇ **Drug-Induced Effect on Nutrient Function, Supplementation Contraindicated, Professional Management Appropriate**

Probability:
4. Plausible

Evidence Base:
☐ **Inadequate**, possibly
○ **Preliminary**

Effect and Mechanism of Action

Alprazolam is a gamma-aminobutyric acid (GABA) agonist known to decrease ACTH and cortisol concentrations. DHEA is secreted synchronously with cortisol by the adrenal glands and demonstrates diurnal variation. Meanwhile, concentrated in limbic regions, in levels much higher than other steroids, DHEA has been postulated to function as an excitatory neuroregulator, antagonizing GABA transmission, based largely on in vitro research. Further, in animal studies, DHEA has been reported to inhibit CYP4A and CYP3A23, which might reduce capacity for metabolism of alprazolam, triazolam, and related medications. Conversely, alprazolam appears to increase circulating DHEA concentrations. The effects of elevated DHEA levels on liver microsomal drug metabolism could

lead to unintentionally elevated circulating levels of these benzodiazepine medications and thereby increase risks associated with adverse effects.

Research

In a study involving 28 healthy men, Kroboth et al.[4] observed that a single intravenous (IV) dose of alprazolam produced (1) significant increases in DHEA concentrations at 7 hours in both young and elderly men; (2) significant decreases in cortisol concentrations; and (3) no change in DHEA-S concentrations. In the authors' interpretation, such findings suggest that alprazolam modulates peripheral concentrations of DHEA and that DHEA and DHEA-S may have an in vivo role in modulating GABA receptor–mediated responses.

Preliminary studies on human liver microsomes in vitro and after administration of 200 mg DHEA daily for 2 weeks to 13 elderly men and women (>65 years old) suggest that DHEA can inhibit CYP3A-mediated metabolism of triazolam. In particular, the findings of Frye et al.[5] suggest that use of exogenous DHEA may thereby increase the risk for adverse effects of triazolam.

Clinical Implications and Adaptations

The interaction between elevated DHEA levels, endogenous or from oral administration, and benzodiazepines such as alprazolam or triazolam appears to be multifaceted and potentially of clinical significance, but currently available research findings are fragmentary and inconclusive. The alprazolam research indicates the value of further investigation into the relationships among DHEA, GABA, ACTH, and cortisol, especially in relation to pharmaceutical agents, but remains inadequate to provide a basis for clinically reliable and therapeutically applicable conclusions. Similar limitations in the research on triazolam call for further investigation into the character and significance of the plausible interaction with DHEA. Given the limited character of the various subject populations, their small number, and the preliminary nature of the experiments, it would be premature to declare the available studies as offering any conclusive evidence regarding potential interaction patterns. The evolution of research in this area points to the need for further investigation into the character of the plausible interactions and their significance.

Pending further research, it would be prudent to avoid concomitant DHEA in individuals on benzodiazepine therapy, particularly with alprazolam or triazolam, because of the theoretical risks of adverse effects from potentially inhibited drug metabolism, heightened DHEA levels, and further derangement of regulatory mechanisms. However, any potential interaction is likely to be slow in onset and manageable with appropriate supervision.

Amlodipine

Amlodipine (Norvasc); combination drug: amlodipine and benazepril (Lotrel).

Interaction Type and Significance

⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

Probability: **3. Possible**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

This interaction has two elements: (1) the effect of androgenic hormones on cardiovascular risk factors in general, and the atherogenic process in particular, and (2) the relationship between amlodipine and these hormones.

Research

Beer et al.[6] found that amlodipine increases serum DHEA-S and androstenedione levels and decreases circulating cortisol in insulin-resistant, obese men with hypertension.

A literature review by Porsova-Dutoit et al.[7] concluded that men with low plasma DHEA and DHEA-S levels were susceptible to increased risk of developing a fatal cardiovascular event; in contrast, evidence was lacking for a protective role of DHEA and DHEA-S in women. The androgenic hormones, especially DHEA-S, can modify the lipid spectrum through their influence on enzymes such as glucose-6-phosphate dehydrogenase (G6PD). These hormones can inhibit human platelet aggregation, enhance fibrinolysis, slow down cell proliferation, improve endothelial function and insulin sensitivity, and reduce plasma levels of plasminogen activator inhibitor type I and tissue plasminogen activator antigen.[8,9]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The action by which amlodipine increases serum DHEA-S and androstenedione levels and decreases circulating cortisol may represent significant components of the mechanism by which the medication improves glucose tolerance and reduces serum insulin levels.

The effect of amlodipine on DHEA levels could potentially be beneficial in reducing cardiovascular risk factors, particularly insulin resistance and hypertension. However, no specific substantive evidence indicates that the potential enhancement of DHEA specifically provides benefit to patients prescribed amlodipine, or that further augmentation would be appropriate unless indicated by other clinical factors for given individuals.

Anticoagulant Medications

Oral Vitamin K Antagonist Anticoagulants: Anisindione (Miradon), dicumarol, ethyl biscoumacetate (Tromexan), nicoumalone (acenocoumarol; Acitrom, Sintrom), phenindione (Dindevan), phenprocoumon (Jarsin, Marcumar), warfarin (Coumadin, Marevan, Warfilone).
Direct Thrombin Inhibitors: Argatroban, bivalirudin (Angiomax), dabigatran etexilate (Rendix; investigational), desirudin (Iprivask, Revasc), hirudin, lepirudin (Refludan).
Heparin, Unfractionated (UFH): Heparin (Calciparine, Hepalean, Heparin Leo, Minihep Calcium, Minihep, Monoparin Calcium, Monoparin, Multiparin, Pump-Hep, Unihep, Uniparin Calcium, Uniparin Forte).
Heparinoids: Danaparoid (Orgaran), fondaparinux (Arixtra).
Low-Molecular-Weight (LMW) Heparin: Ardeparin (Normiflo), certoparin (Mono-Embolex), dalteparin (Fragmin), enoxaparin (Clexane, Lovenox), nadroparin (Fraxiparine), tinzaparin (Innohep).

Interaction Type and Significance

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

Probability: **4. Plausible**

Evidence Base: ▽ **Mixed**

Effect and Mechanism of Action

The research literature investigating the relationship of endogenous DHEA-S levels, fibrinolysis, and coagulation offers mixed conclusions and provides inadequate evidence for determining a consistent mechanism of any potential interaction between supplemental DHEA and anticoagulant medications.

Research

This frequently mentioned adverse interaction is based on DHEA's supposed action as a blood thinner and as a potential cause of increased clotting. However, searches for primary research yield little direct substantive evidence of a consistent and clinically relevant pattern of interaction.

A study by Nilsson et al.[10] (1985) of 33 men undergoing major abdominal surgery investigated the role of steroid hormones in regulation of extrinsic fibrinolysis and found that DHEA-S levels were the single correlation that distinguished patients with postoperative deep vein thrombosis from those without this complication. However, they could offer no explanation in terms of hemostatic mechanisms for this finding.

Clinical Implications and Adaptations

This potential interaction is derived from studies that have reported DHEA affecting clotting. Such action raises concern that exogenous DHEA intake might alter the effects of anticoagulant medications and possibly the therapeutic dose.

If a strong relationship exists between increased cardiovascular risk and decreased DHEA/DHEA-S levels, particularly in men, it does not necessarily follow that administration will reduce such risk. However, if as proposed, DHEA provides a significant antiatherogenic effect and fibrinolytic action, the same mechanism might also confuse the predicted outcomes of anticoagulant dosing. Nevertheless, any such "excessive" DHEA intake would presumably be less likely in individuals with lower endogenous DHEA/DHEA-S levels and, as indicated by the research, could exert a differential effect in men versus women. Furthermore, regular INR testing and avoidance of any sudden or dramatic levels of DHEA intake would be critical elements of any therapeutic agenda incorporating DHEA concurrent with warfarin therapy, or a PTT/anti-Xa activity for any of the heparin-related compounds. Such gradual increase and decrease of DHEA dosing levels is typical of prescribing patterns when DHEA has been used clinically by health care professionals experienced in nutritional therapeutics; in cases involving anticoagulants, caution, close monitoring, and gradual prescription alterations would be even more necessary.

Anticonvulsant Medications, Including Phenobarbital, Phenytoin, and Valproic Acid

Carbamazepine (Carbatrol, Tegretol), clonazepam (Klonopin), clorazepate (Tranxene), divalproex semisodium, divalproex sodium (Depakote), ethosuximide (Zarontin), ethotoin (Peganone), felbamate (Felbatol), fosphenytoin (Cerebyx, Mesantoin), levetiracetam (Keppra), mephenytoin, mephobarbital (Mebaral), methsuximide (Celontin), phenobarbital (phenobarbitone; Luminal, Solfoton), phenytoin (diphenylhydantoin; Dilantin, Phenytek), piracetam (Nootropyl), primidone (Mysoline), sodium valproate (Depacon), topiramate (Topamax), trimethadione (Tridione), valproate semisodium, valproic acid (Depakene, Depakene Syrup), vigabatrin (Sabril), zonisamide (Zonegran).

Similar properties but evidence indicating no or reduced interaction effects: Oxcarbazepine (GP 47680, oxycarbamazepine; Trileptal).

Similar properties but evidence lacking for extrapolation: Acetazolamide (Diamox, Diamox Sequels).

Interaction Type and Significance

✗✗✗ Potentially Harmful or Serious Adverse Interaction—Avoid

Probability:
4. Plausible

Evidence Base:
☐ **Inadequate**

Effect and Mechanism of Action

Carbamazepine, phenytoin, and other CNS agents induce the P450 enzymes, particularly CYP3A4, that metabolize DHEA and DHEA-S and therefore decrease circulating concentrations of these hormones.[11-14] Although related to carbamazepine, opinion is mixed as to whether oxycarbamazepine induces hepatic phase 1 microsomal enymes.[15] Further, concomitant DHEA has been reported to interfere with the action of anticonvulsant medications. Additionally, some have suggested that DHEA should be deemed as sharing the same risk profile as anabolic steroids in their ability to aggravate or induce significant psychiatric difficulties, including mania, impaired cognition, and overt psychosis; evidence for any specific mechanisms has usually been lacking.

Research and Reports

Some preliminary human studies and scattered case reports indicate a possible role of elevated DHEA levels in cases of mania and aggravation of bipolar disorder diathesis.[16] Although some of this research focuses on endogenous levels, at least one frequently cited case report of an "interaction" involved oral DHEA and an anticonvulsant medication, even though the valproic acid (VPA) was prescribed in relation to symptoms presumed to be caused by the DHEA and was initiated after the DHEA intake was discontinued. In that case, Markowitz et al.[17] reported mania in an older man acutely admitted to a psychiatric facility with no previous personal or family history of bipolar disorder, apparently related to 6 months' prior use of 200 to 300 mg DHEA daily. The patient responded favorably to 7-day inpatient hospitalization and 500 mg VPA twice daily.[17] In another case report, Dean[18] reported on a 31-year-old man with a history of alcohol abuse, violent anger, and an unsubstantiated diagnosis of bipolar disorder, who became threatening after taking an estimated 100 mg (unprescribed) sertraline and 300 to 500 mg DHEA daily for several weeks. This patient improved with valproate therapy.[18]

Although not necessarily demonstrating an authentic adverse interaction involving exogenous DHEA, these events suggest that one action by which some anticonvulsant medications may suppress an episode of mania could be by lowering circulating DHEA-S concentrations. Such events do reinforce continued cautions against the use of multiple potentially psychoactive substances by individuals with a history of violence or unstable emotional states without close monitoring by a qualified health care professional.

Clinical Implications and Adaptations

Dehydroepiandrosterone is deeply involved in the hypothalamic-pituitary axis, limbic function, and cortisol cycles, so it is reasonable to look for associations between DHEA-S levels and mental-emotional disturbances. Elevated DHEA levels may inhibit the therapeutic action of anticonvulsant medications; concomitant use of DHEA, particularly in doses greater than 100 mg/day and among men under 40 years of age, is generally contraindicated. Such medications may lower circulating DHEA concentrations, but use of exogenous DHEA could theoretically lead to adverse effects. However, if an individual has been stable while taking both agents simultaneously, it would be prudent to maintain current levels unless otherwise indicated, and if cessation of DHEA intake is deemed appropriate, such changes should be gradual and closely monitored.

Clonidine and Fluoxetine

Clonidine (Apo-Clonidine, Catapres Oral, Catapres-TTS Transdermal Dixarit, Duraclon; Novo-Clonidine, Nu-Clonidine); combination drug: clonidine and chlorthalidone (Combipres); fluoxetine (Prozac, Sarafem).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

DHEA may restore the response of beta-endorphin, a key neuropeptide, to clonidine and fluoxetine.

Research

As part of their investigation of endocrine, neuroendocrine, and behavioral effects of oral DHEA-S administration in postmenopausal women, Stomati et al.[19] evaluated plasma beta-endorphin levels in response to neuroendocrine tests using clonidine, fluoxetine, and naloxone. After 3 months of 50 mg/day DHEA-S, the women in this small study demonstrated a restored response of the beta-endorphin to clonidine and fluoxetine. The authors concluded that their research "suggests that DHEAS and/or its active metabolites modulates the neuroendocrine control of pituitary beta-endorphin secretion."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The previous research indirectly suggests a potential therapeutic benefit from coordinated use of DHEA adjunctively with clonidine or fluoxetine. However, although based on solid evidence, the cited research did not specifically address the issue of interactions between DHEA and these pharmaceutical agents. the rationale for this potential supportive interaction is consistent with known data, but further research is required to determine whether such concomitant use provides therapeutic efficacy and how best to coordinate such integrative therapeutic strategies, if clinical evidence supporting implementation of such a strategy should emerge.

Corticosteroids, Oral

Betamethasone (Celestone), cortisone (Cortone), dexamethasone (Decadron), fludrocortisone (Florinef), hydrocortisone (Cortef), methylprednisolone (Medrol) prednisolone (Delta-Cortef, Orapred, Pediapred, Prelone), prednisone (Deltasone, Liquid Pred, Meticorten, Orasone), triamcinolone (Aristocort). Similar properties but evidence lacking for extrapolation: Inhalant and topical corticosteroids.

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
1. Certain

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action

Oral corticosteroid therapy has been demonstrated to lower serum levels of DHEA and DHEA-S significantly. Some corticosteroid agents, such as dexamethasone, affect the hypothalamic-pituitary-adrenal (HPA) axis by inhibiting ACTH and therefore decrease DHEA and DHEA-S concentrations. Beclomethasone and budesonide may also induce such an effect.

The presence of exogenous corticosteroids from use of prednisone or related drugs can confuse the internal hormonal regulatory processes. If the pituitary senses that corticosteroid levels are higher than normal, the regulatory feedback loops send a signal to decrease the production of ACTH and thus reduce the levels of several key hormones. As a consequence of these changes in hormonal balance, the internal stimulation to produce DHEA can often fall, androgen levels can rise, and the cascade of adverse effects, such as muscle wasting, ensue.

Several researchers have suggested that DHEA depletion might constitute an aspect of corticosteroid-induced osteoporosis. DHEA may also increase the effects of prednisolone.

Research

Relatively early research by Judd et al.[20] (1977) correlated dexamethasone administration with severely lowered serum concentrations of DHEA and DHEA-S. A later study by Smith et al.[21] (1994) found that beclomethasone administration for asthma suppressed DHEA-S in postmenopausal women. This particular pattern raises the concern as to the respective roles of corticosteroids and DHEA on bone density and iatrogenic osteoporosis, especially among postmenopausal women, and suggests the value of continued research to clarify this clinically important drug-induced adverse effect and potential adjunctive therapeutics using concomitant DHEA. Studies led by Riedel et al.[22] and Rosen et al.[23] found impaired well-being in patients with adrenal insufficiency despite adequate replacement of glucocorticoids and mineralocorticoids. Further, a landmark study of middle-aged subjects by Morales et al.[24] suggested that DHEA administration might positively influence well-being. Thus, effects of DHEA on well-being and mood became a plausible target for studies in adrenal insufficiency. A literature review conducted by Robinzon and Cutolo[25] focused on the issue of the clinical efficacy of DHEA replacement therapy adjunctively with glucocorticoid therapy and concluded that the evidence suggests that DHEA concomitant may counteract adverse effects caused by long-term administration of steroidal agents. As with much of the evolving research on therapeutic corticosteroids, the risk of interaction and nutrient depletion is significantly greater with oral medications than with inhalant and topical steroids. Nevertheless, studies by Nadeau et al.[26] and Toogood et al.[27] observed adverse effects on several key metabolic factors, including DHEA levels, subsequent to treatment with high-dose inhaled corticosteroids, particularly budenoside.

DHEA and DHEA-S levels tend to be low in individuals prescribed corticosteroids, before therapy,[25,28,29] and administration of DHEA adjunctively during (and possibly after) corticosteroid therapy does not appear to interfere with therapeutic action of the drug, and may enable reduction of medication levels, and thus adverse drug effects, without compromising therapeutic efficacy. Straub et al.[30] investigated and confirmed that individuals with chronic inflammatory diseases, for which corticosteroids are typically prescribed, demonstrated significantly lower serum concentrations of the sulfated form of DHEA (DHEA-S). Meno-Tetang et al.[30a] found that multiple dosing of 200 mg oral DHEA produced serum concentrations of DHEA and DHEA-S significantly greater than endogenous levels, while also increasing serum androstenedione and

testosterone levels. Such effect did not alter either single-dose oral prednisolone pharmacokinetics or inhibition of cortisol secretion by prednisolone. In a more recent study (2002) involving 191 women undergoing corticosteroid therapy for systemic lupus erythematosus (SLE), Petri et al.[31] reported that concomitant administration of 200 mg DHEA daily allowed for reduced dosage of prednisone "for a sustained period of time while maintaining stabilization or a reduction of disease activity was possible in a significantly greater proportion of patients . . . , compared with patients treated with placebo." Nordmark[32] and colleagues conducted a double-blind, randomized, placebo-controlled study involving 41 women with SLE who were taking at least 5 mg prednisolone daily. The investigators followed the women for 6 months, during which they took placebo, 30 mg of DHEA daily if age 45 or younger, or 20 mg of DHEA daily if age 46 or older. After the double-blind period, the investigators followed the women for an additional 6-month open phase and offered the treatment to all the patients. In findings presented at the European Congress of Rheumatology (EULAR) in June 2004, the researchers reported that serum levels of sulfated DHEA increased in women treated with DHEA; the mean level at baseline was subnormal, but levels were in the normal range after treatment. Both subjects and their partners reported improvement in several quality-of-life parameters in association with DHEA coadministration. No adverse effects were associated with DHEA use; however, high-density lipoprotein (HDL) cholesterol decreased and insulin-like growth factor (IGF-1) and hematocrit increased. Nordmark et al.[33] later published their final findings and concluded that "low dose DHEA treatment improves HRQOL [health-related quality of life] with regard to mental well-being and sexuality and can be offered to women with SLE where mental distress and/or impaired sexuality constitutes a problem."

The evidence for this pattern of drug-induced depletion appears consistent, but research has focused on only a few medications within this drug class. Therefore, caution must be exercised in extrapolating these research findings to all corticosteroid agents generally, particularly in light of the wide range of individual variability and key factors, such as gender, life stage, medical condition, and polypharmaceutical prescribing.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Although the evidence of corticosteroid therapy's adverse effect on DHEA/DHEA-S generally approaches consensus, there is only an emerging sense of therapeutic appropriateness concerning the efficacy and clinical protocols for compensatory DHEA administration.[34] As mentioned, the review by Robinzon and Cutolo[25] suggested the clinical benefit of concomitant DHEA, but such therapeutic approaches, particularly as part of a conscious and coherent integrative strategy, have not even broached consideration in standard clinical practice guidelines.

Individuals using corticosteroids for extended periods should consult with their prescribing physician and/or a nutritionally trained health care professional about the potential benefits of concomitant DHEA to prevent muscle wasting without losing the anti-inflammatory effect of prednisone. Laboratory tests can determine the degree to which endogenous DHEA has been adversely affected and suggest an appropriate dosage level, if needed.

Continued investigation is warranted to determine if and when concomitant DHEA may be beneficial to individuals using corticosteroids, both oral and inhaled, and at what levels, when deemed therapeutically appropriate.

ESTROGENS, PROGESTINS, AND ESTROGEN-PROGESTIN COMBINATIONS

Oral Contraceptives: Monophasic, Biphasic, and Triphasic Estrogen Preparations (Synthetic Estrogen and Progesterone Analogs)

Ethinyl estradiol and desogestrel (Desogen, Ortho-TriCyclen).
Ethinyl estradiol and ethynodiol (Demulen 1/35, Demulen 1/50, Nelulen 1/25, Nelulen 1/50, Zovia).
Ethinyl estradiol and levonorgestrel (Alesse, Levlen, Levlite, Levora 0.15/30, Nordette, Tri-Levlen, Triphasil, Trivora).
Ethinyl estradiol and norethindrone/norethisterone (Brevicon, Estrostep, Genora 1/35, GenCep. 1/35, Jenest-28, Loestrin 1.5/30, Loestrin1/20, Modicon, Necon 1/25, Necon 10/11, Necon 0.5/30, Necon 1/50, Nelova 1/35, Nelova 10/11, Norinyl 1/35, Norlestin 1/50, Ortho Novum 1/35, Ortho Novum 10/11, Ortho Novum 7/7/7, Ovcon-35, Ovcon-50, Tri-Norinyl, Trinovum).
Ethinyl estradiol and norgestrel (Lo/Ovral, Ovral).
Mestranol and norethindrone (Genora 1/50, Nelova 1/50, Norethin 1/50, Ortho-Novum 1/50).
Related, Internal Application: Etonogestrel/ethinyl estradiol vaginal ring (Nuvaring).

Hormone Replacement Therapy (HRT): Estrogen-Containing and Synthetic Estrogen and Progesterone Analog Medications

HRT, estrogens: Chlorotrianisene (Tace); conjugated equine estrogens (Premarin); conjugated synthetic estrogens (Cenestin); dienestrol (Ortho Dienestrol); esterified estrogens (Estratab, Menest, Neo-Estrone); estradiol, topical/transdermal/ring (Alora Transdermal, Climara Transdermal, Estrace, Estradot, Estring FemPatch, Vivelle-Dot, Vivelle Transdermal); estradiol cypionate (Dep-Gynogen, Depo-Estradiol, Depogen, Dura-Estrin, Estra-D, Estro-Cyp, Estroject-LA, Estronol-LA); estradiol hemihydrate (Estreva, Vagifem); estradiol valerate (Delestrogen, Estra-L 40, Gynogen L.A. 20, Progynova, Valergen 20); estrone (Aquest, Estragyn 5, Estro-A, Estrone '5', Kestrone-5); estropipate (Ogen, Ortho-Est); ethinyl estradiol (Estinyl, Gynodiol, Lynoral).
HRT, estrogen/progestin combinations: Conjugated equine estrogens and medroxyprogesterone (Premelle cycle 5, Prempro); conjugated equine estrogens and norgestrel (Prempak-C); estradiol and dydrogesterone (Femoston); estradiol and norethindrone, patch (CombiPatch); estradiol and norethindrone/norethisterone, oral (Activella, Climagest, Climesse, FemHRT, Trisequens); estradiol valerate and cyproterone acetate (Climens); estradiol valerate and norgestrel (Progyluton); estradiol and norgestimate (Ortho-Prefest).
HRT, estrogen/testosterone combinations: Esterified estrogens and methyltestosterone (Estratest, Estratest HS).

Interaction Type and Significance

- ✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**
- ⊕✗ **Bimodal or Variable Interaction, with Professional Management**
- ⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

Probability: **3. Possible**

Evidence Base: ☐ **Inadequate**

Effect and Mechanism of Action

As a precursor steroid, DHEA can be converted into estrogen (or progesterone), and exogenous DHEA intake has been

shown to increase levels of female reproductive hormones. Serum DHEA/DHEA-S concentrations are likely to be lower among women in the life stages during which HRT is typically prescribed. Exogenous estrogen compounds might also induce lowered levels of endogenous DHEA through their impact on endocrine regulatory mechanisms. Either pattern of disruption in normal homeostatic processes could cause symptoms of hormonal dysfunction and imbalance.

Research

Mortola and Yen[35] investigated the effect of 12-month DHEA replacement therapy in 14 women age 60 to 70 who received daily applications of a 10% DHEA cream. They observed a beneficial effect on vaginal epithelium maturation in most of the women attributable to the estrogenic effect of DHEA and significantly increased hip bone mineral density (BMD), accompanied by an increase in serum osteocalcin. In contrast, they noted a lack of estrogenic effect from the DHEA on the endometrial tissue, which remained atrophic in all women.[35] Nevertheless, no substantive evidence is available concerning the likelihood, significance, and outcome(s) of this plausible interaction for a range of medications and involving populations with varied characteristics.

Clinical Implications and Adaptations

Given the inherent nature of estrogen and DHEA, their combined use within a coordinated integrative strategy suggests a reasonable likelihood of value in enhancing therapeutic efficacy and possibly reducing potential adverse effects associated with HRT. However, by the same additive effect, concomitant administration of estrogen hormone therapies and DHEA, in theory, may induce increased adverse effects resulting from excessively elevated levels of either hormone. The combination of DHEA with compounded "tri-est" formulations (mixtures of estrone, estradiol, and estriol, often in a 1:1:8 ratio) has been used in clinical practice for many years by physicians implementing integrative therapeutics strategies. Even though preliminary clinical research suggests potential for emergent integrative therapeutics, particularly in the treatment of menopausal women, the direct effects of the potential interaction between exogenous estrogen medications and DHEA has not yet been studied in a thorough and systematic manner translatable into clear and consistent clinical practice guidelines. The concomitant use of these two therapeutic approaches could be either beneficial or adverse, depending on the individual, health status, relative dosage levels, and resultant blood and tissue levels. Close clinical management and regular monitoring by a health care professionals experienced in both conventional pharmacology and nutritional therapeutics are warranted during concomitant use of these substances.

Methyltestosterone and Related Androgens

Methyltestosterone (Android, Methitest, Testred, Virilon). Extrapolated, based on similar properties: Methyltestosterone combination drug: methyltestosterone and esterified estrogens (Estratest, Estratest HS).

Androgens: Fluoxymesterone (Halotestin), testolactone (Testolacton; HSDB 3255, SQ 9538; Fludestrin, Teolit, Teslac, Teslak), testosterone cypionate.

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

Probability:
2. Probable

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action

As a precursor steroid, DHEA can be converted into testosterone, and exogenous DHEA intake has been shown to increase levels of circulating androgens. Thus, administration of both methyltestosterone (or testosterone) and exogenous DHEA could each independently increase testosterone levels. Intentional additive interaction could be therapeutically efficacious, whereas uncoordinated concurrent use could theoretically induce excessive testosterone levels and attendant adverse effects and elevated risk factors.

Research

Many studies have demonstrated the effects of DHEA administration on androgen levels and noted differentials effects based on gender and age, preintervention deficiency states, health status, and other factors.[36–38] For example, in a randomized, placebo-controlled crossover trial, Morales et al.[39] administered a 50-mg nightly oral dose of DHEA to 13 men and 17 women, age 40 to 70, over 6 months. They reported a restoration of DHEA and DHEA-S serum levels to those found in young adults within 2 weeks of DHEA replacement, and a twofold increase in serum levels of androgens (androstenedione, testosterone, and dihydrotestosterone) in women, with only a small rise in androstenedione in men. Later, Wolfe et al.[40] administered 50 mg daily DHEA to 40 healthy elderly men and women, all of whom had low DHEA-S baseline levels. DHEA augmentation leads to a fivefold increase in DHEA-S levels in women and men. DHEA, androstenedione, and testosterone levels also increased significantly in both genders.

Despite the plethora of research relating to interrelationships between endogenous DHEA and steroid hormones, including testosterone, no substantive human clinical research has yet directly investigated the effects, methods, and implications of concomitant use of DHEA and testosterone (or methyltestosterone), either deliberately or unintentionally. The need for and potential value of such research are clearly indicated by patient needs, the extant literature, and emerging clinical practice, particularly in the turbulent and reconfiguring realm of hormone therapy related to menopause and other aspects of aging.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Simultaneous use of DHEA and testosterone presents a clinically significant, though as-yet inadequately investigated, example of the potential for a drug-nutraceutical interaction to induce beneficial or adverse effects and thereby require qualified clinical management. DHEA and testosterone are often prescribed together for menopausal women with diminished libido in conjunction with tri-est formulations within individualized compounded pharmaceutical preparations.[41] A similar but simpler approach is embodied in the combination drug Estratest/Estratest HS. Such formulations are typically individually formulated and prepared in conjunction with a compounding pharmacist, and the doses and constituent proportions evolve over time in response to therapeutic effect and clinical strategy. Recent research indicates that the apolipoprotein E (ApoE) gene determines serum testosterone and DHEA levels in postmenopausal women.[42] Thus, pharmacogenomic factors need to be considered in determining hormonal deficiency patterns, response to medications, and risk of adverse effects, including genetic susceptibility to and

family history of breast cancer. In cases where methyltestosterone has been prescribed for men diagnosed with testosterone deficiency, DHEA therapy could also be considered as indicated. Endogenous levels, relative doses, mode of administration, health status, gender and life stage, concomitant polypharmacy, and other factors, as well as the as-yet inadequately predictable response of the individual's endocrine regulatory processes, will all influence the probability, clinical significance, and character of any resultant interaction.

While offering an opportunity for synergistic prescribing and innovative therapeutic strategies to individualized and evolving integrative care, concomitant use of testosterone (or methyltestosterone) and DHEA demands close supervision and regular monitoring. Even though methyltestosterone can be used in the treatment of breast cancer, such combined use would be therapeutically inappropriate and contraindicated for women (or men) with a personal or family history of or genetic susceptibility to breast cancer, because DHEA may also be converted to either estrogen or progesterone. Likewise, administration of either or both substances is contraindicated for men with a personal or family history of or genetic susceptibility to prostate cancer. DHEA is currently being studied as a potential primary and secondary chemopreventive agent in women at high risk for breast cancer, but results of these studies are not yet available.

Zidovudine (AZT) and Related Reverse-Transcriptase Inhibitor (Nucleoside) Antiretroviral Agents

Evidence: Zidovudine (azidothymidine, AZT, ZDV, zidothymidine; Retrovir); combination drugs: zidovudine and lamivudine (Combivir); abacavir, lamivudine, and zidovudine (Trizivir).
Extrapolated, based on similar properties: Abacavir (Ziagen), didanosine (ddI, dideoxyinosine; Videx); dideoxycytidine (ddC, zalcitabine; Hivid), lamivudine (3TC, Epivir), stavudine (D4T, Zerit), tenofovir (Viread).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Deficiencies in testosterone, estradiol, and growth hormone (GH) can be associated with depression or dysthymia. DHEA acts as a precursor to testosterone and estradiol, both of which are known to exert a beneficial effect on mood when administered exogenously. DHEA also increases available levels of insulin-like growth factor, which in turn can elevate GH levels. Furthermore, DHEA may modulate tumor necrosis factor and other inflammatory cytokines, an excess of which are associated with cachexia in HIV disease and cancer. These factors can be especially significant in individuals with HIV infection, in whom declines in DHEA levels can be associated with the progression to AIDS. Potential supportive effects of coadministration on therapeutic response to antiretroviral agents have been proposed, but mechanisms of action have not been elucidated or confirmed.

Research

Preliminary research in vitro and with mice has indicated a potential synergistic interaction from coordinated, concomitant use of AZT and DHEA, as indicated by enhanced effectiveness of AZT against HIV-infected cells and as part of cisplatin-based chemotherapy against colorectal adenocarcinoma.[43,44] Although encouraging, such laboratory studies suggest the value of further research, particularly randomized clinical trials, more than they offer a solid basis for clinical experimentation or evidence-based practice.

Subsyndromal major depressive disorder is common among HIV-positive adults, particularly physically ill patients undergoing current multidrug antiretroviral regimens (HAART). In a randomized, placebo-controlled trial, Rabkin et al.[45] administered either DHEA, using flexible dosing of 100 to 400 mg daily, or placebo to 145 patients with subsyndromal depression or dysthymia, 80% of whom were receiving concurrent antiretroviral treatment. Using both a Clinical Global Impression improvement rating and a final Hamilton Depression Rating Scale score, the response rate was 62% (43 of 64) for the DHEA group, compared to 33% (21 of 64) for the placebo patients. Few adverse events and no significant changes in CD4 cell count or HIV RNA viral load were reported in either treatment group. DHEA may be particularly important for HIV-positive pre-AIDS patients, because declining levels of DHEA have been associated with progression to AIDS in both cross-sectional comparisons of HIV-positive men and women at different stages of HIV illness and in longitudinal studies. Further, the authors noted: "The low attrition rate in this group of physically ill patients, together with requests for extended open-label treatment, reflect high acceptance of this readily available intervention."[45]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians providing treatment to HIV-positive individuals exhibiting nonmajor depression are advised to consider coadministration of DHEA (100-200 mg twice daily), particularly in patients who are unwilling to use conventional antidepressants. The available research findings are limited but significant, and the probability of adverse effects is minimal. Further research through well-designed, adequately powered clinical trials, with more diverse subject population and long-term follow-up on maintenance of response or possible long-term endocrine or other effects of DHEA, appears warranted.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

In their valuable review of the influence of hormones and pharmaceutical agents on DHEA-S concentrations, Salek et al.[46] noted that although exogenous DHEA intake increases circulating DHEA and DHEA-S concentrations, "the kinetics does not appear to be the same as with endogenous secretion."

Evidence indicates that a wide range of medications may lower DHEA and DHEA-S levels, but no adequate investigation has yet determined whether clinically significant depletion patterns result. Further, given the complex interdependencies among hormones and their multiple feedback systems, it is premature to speculate, in most circumstances, whether administration of DHEA might be therapeutically appropriate, even in instances of probable drug-induced depletion. Likewise, the adverse consequences of excess androgen concentrations and the likely attendant disruptions in related hormone levels and interrelationships emphasize the need for caution in considering dosage levels that might result in excessive concentrations of DHEA and DHEA-S. Such considerations are further complicated by the variable nature of DHEA concentration and functions in diverse human populations, especially based on gender and life stage, and by individual biochemical and

pharmacogenomic variability, particularly in the context of disease, aging, and physiological dysfunction.

The action of endogenous DHEA and DHEA-S and exogenous oral DHEA on blood glucose and insulin levels, hepatic enzyme systems, atherogenesis, endothelial function, coagulation and fibrinolytic processes, sex steroid and other hormone levels, as well as myriad other metabolic functions creates many potential interactions with several classes of pharmaceutical agents. The scientific discourse and clinical research cannot yet substantively answer most of the potential questions as to whether these interactions are frequent or rare, significant or negligible, and adverse, neutral, or beneficial. Within this context of complexity and variability where animal and in vitro research are fundamentally inadequate to understand conclusively the therapeutics of DHEA, any discussion of interactions is inherently even more theoretical, extrapolated, and speculative.

Antidepressant and Stimulant Medications

Antidepressant and Stimulant Medications

Some broad concerns have been expressed declaring risks of adverse interactions from concomitant use of DHEA with antidepressants and CNS stimulants. Although such theoretical interactions are plausible, especially with extremely high doses of DHEA in unstable individuals outside the context of close clinical management, they are as yet not supported by a significant or substantial body of scientific evidence, especially drawn from clinical human studies. Some secondary sources have cited papers on "mania" supposedly associated with DHEA supplementation by Dean, Markowitz, and others, with unclear case reports and presumptions of linkage to intake of steroidal hormones other than DHEA. In their discussion of one case, Markowitz et al.[17] note that the association of mania with both tricyclic antidepressants and selective serotonin reuptake inhibitors was "well-known" but then explicitly declared as "speculative" the hypothesis that DHEA might induce mania based on such a possible mechanism and that of elevated androgenic steroid levels. Critical examination of the literature renders such concerns as potentially worthy of further investigation, but claims of definitive causation are premature and unsubstantiated. If, as suggested by some authors, DHEA exercises a serotonergic action on the CNS, such effect might function therapeutically but would form the basis of a potentially adverse additive interaction, in the absence of proper clinical management. Other writers have cited the numerous studies examining DHEA as potentially elevating mood and enhancing feelings of well-being in research on depression, Addison's disease, aging, menopause, and other conditions, as grounds for supposed risk of adverse interactions from a presumed additive effect. Any such assertions appear to be premature, speculative, and potentially misleading. Although the unsupervised use of DHEA in supraphysiologic doses by individuals under pharmacological therapy, especially those with a psychiatric diagnosis, is imprudent and deserving caution, substantial evidence of significant clinical risk is lacking.

Oral Hypoglycemic Agents and Insulin

Buformin (Andromaco Gliporal, Buformina), chlorpropamide (Diabinese), glimepiride (Amaryl), glipizide (Glucotrol; Glucotrol XL), glyburide (glibenclamide; Diabeta, Glynase, Glynase Prestab, Micronase, Pres Tab), insulin (animal-source insulin: Iletin, human analog insulin: Humanlog; human insulin: Humulin, Novolin, NovoRapid, Oralin), metformin (Dianben, Glucophage, Glucophage XR); combination drugs: glipizide and metformin (Metaglip); glyburide and metformin (Glucovance); tolazamide (Tolinase), phenformin (Debeone, Fenformin), tolbutamide (Orinase, Tol-Tab).

Insulin acts as a physiological regulator of DHEA sulfate metabolism and lowers circulating DHEA-S concentrations, especially in men. Insulin administration has been found to decrease the concentration of circulating DHEA and DHEA-S. Meanwhile, DHEA can stimulate the production of insulin-like growth factor-1 (IGF-1), a hormone that stimulates anabolic metabolism, improves insulin sensitivity, and otherwise affects insulin- and glucose-related metabolic processes. Such relationships suggest that exogenous DHEA administration might alter blood glucose regulation and interact with several medications. Related research indicates that DHEA intake might reduce risk or enhance treatment of glucose dysregulation and could counter an insulin-induced DHEA depletion pattern. In the absence of informed supervision, such influences could disturb the intended effects of insulin, metformin, or oral hypoglycemics such as sulfonylureas and require modification in the therapeutic dose.

The findings of a small study by Lavallee et al.[47] involving infusion of DHEA and insulin suggest that insulin increases the metabolic clearance rate of DHEA by stimulating its conversion to DHEA fatty acid esters (DHEA-FA) and by enhancing uptake of DHEA-FA by peripheral tissues. Nestler et al.[48] investigated the effect of oral administration of metformin three times daily over 21 days on 28 nondiabetic men. Metformin administration resulted in significant reductions in serum insulin levels and concurrent increases in serum DHEA-S levels. Higher levels of DHEA-S may be part of the beneficial effects of metformin in relation to insulin and glucose regulation. DHEA use enhances endothelial function and insulin sensitivity in men. In a study of 24 older men with hypercholesterolemia, randomized to receive DHEA (25 mg/day) or placebo for 12 weeks, Kawano et al.[9] found that DHEA treatment, but not placebo, was associated with a significant improvement in endothelial function, an effect apparent within 4 weeks of beginning treatment. The DHEA augmentation also produced a significant drop in steady-state glucose levels, without altering insulin levels. The duration of DHEA use was inversely tied to levels of plasminogen activator inhibitor type 1, another protective effect within the cardiovascular system.

Even with this emerging insight into several mechanisms that may help explain DHEA's antiatherosclerotic effect, substantive evidence is still needed, based on human clinical studies using oral DHEA with insulin-dependent diabetic individuals, that directly confirms a consistent pattern of interaction, either adverse or beneficial. Pending further research, individuals undergoing insulin or metformin therapy are advised to avoid DHEA intake outside the context of integrative therapeutic care with close supervision and regular monitoring by health care professionals experienced in both conventional pharmacology and nutritional therapeutics.

Thyroid Hormones

L-Triiodothyronine (T_3): Cytomel, liothyronine sodium, liothyronine sodium (synthetic T_3), Triostat (injection).
Levothyroxine (T_4): Eltroxin, Levo-T, Levothroid, levothyroxine (synthetic), levoxin, Levoxyl, Synthroid, thyroxine, Unithroid.
L-Thyroxine and L-triiodothyronine ($T_4 + T_3$): animal levothyroxine/liothyronine, Armour Thyroid, desiccated thyroid, Westhroid.
L-Thyroxine and L-triiodothyronine (synthetic $T_4 + T_3$): Euthroid, Euthyral, liotrix, Thyar, Thyrolar.
Dextrothyroxine (Choloxin).

DHEA may potentiate thyroid medications. Animal studies, clinical reports, and reasonable interpretations of known endocrine interrelationships indicate a plausible interaction between thyroid medications (e.g., Synthroid) and orally administered DHEA. Such effect, whether additive or synergistic, might introduce an increased risk of iatrogenic thyrotoxicosis if unintentionally induced, or it might be used to reduce the dose of thyroid medication through concomitant, coordinated administration of DHEA. Because this interaction is plausible given present data and clinical experience, further research is recommended, and concomitant use should be only be undertaken within the context of a coordinated strategy of integrative therapeutics providing for close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapy.

The 49 citations for this monograph, as well as additional reference literature, are located under DHEA on the CD at the back of the book.

Glucosamine Sulfate

Nutrient Name: Glucosamine sulfate.
Synonyms: Glucosamine sulphate; D-glucosamine sulfate potassium salt; GS.
Related Substances: Glucosamine hydrochloride, *N*-acetyl-D-glucosamine (NAG, N-A-G).

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Acetaminophen Ibuprofen Nonsteroidal anti-inflammatory drugs (NSAIDs) ◇≈≈/◇/⊕X/⊕⊕	Coadministration of glucosamine and NSAIDs may enable anti-inflammatory effect at lower drug doses. Concurrent use of glucosamine sulfate (GS) with ibuprofen or ketoprofen appears to result in synergistic effect; other NSAIDs may provide additive effect. Acetaminophen metabolism involves sulfation and thus consumes sulfate provided by GS for glycosaminoglycan synthesis; aspirin may similarly interact to induce subadditive effect. More strategically, NSAIDs may promote cartilage destruction and impair cartilage repair.	Consider ibuprofen rather than acetaminophen when using GS. Coadministration may enable decreased dose and shortened period of NSAID use.
Insulin Oral hypoglycemic agents X	Glucosamine might theoretically accelerate hexosamine pathway and inhibit liver glucokinase because of similarity between glucosamine-6-phosphate and glucose-6-phosphate glucosamine. Such effect might induce changes in glucose metabolism and contribute to insulin resistance. Glucosamine (sulfate or hydrochloride) administration may slightly elevate glucose levels in some individuals, but evidence indicates that it does not alter glucose metabolism, including that of diabetics, to a clinically significant degree, and that clinically significant interactions with insulin or oral hypoglycemic agents are improbable.	Administer glucosamine (sulfate) as indicated. Monitor glucose levels in diabetic individuals as customary.

NUTRIENT DESCRIPTION

Chemistry

D-Glucosamine (2-amino-2-deoxy-D-glucose) is a chemically defined, small molecule (molecular weight, 179.17 daltons) with a pK_a of 6.91. It is an amino-monosaccharide molecule, formed of glucose and an amine moiety, and one of the basic constituents of the disaccharidic units of articular cartilage glycosaminoglycans (GAGs). The amine is positively charged at physiologic pH and will hold a counter anion, either two chlorides or one sulfate.

See also Nutrient Preparations section.

Physiology and Function

Glucosamine plays a central role in determining the strength and resiliency of connective tissue. An amino sugar biosynthesized from glucose, glucosamine is one of the principal substrates used in the biosynthesis of macromolecules that comprise articular cartilage and thus a key compound within the ground substance that makes up connective tissue. Glucosamine is the preferred substrate for biosynthesis of mucopolysaccharides and bipolymers of the articulations and bones and has been reported to facilitate the hexosamine pathway of proteoglycan synthesis by the chondrocytes. It modulates interleukin-1 (IL-1)–induced activation of chondrocytes for cartilage rebuilding and stimulates production of proteoglycans (including therefore the proteic moiety) with a normal polymeric structure while simultaneously inhibiting proteoglycan degradation. Glucosamine also stimulates synthesis of GAGs and collagen, as well as synovial production of hyaluronic acid, which is critical to the lubricating and shock-absorbing properties of synovial fluid. Glucosamine sulfate (GS), in particular, can increase serum sulfate concentrations and thereby elevate synovial fluid sulfate concentrations and enable proteoglycan sulfation.[1] In addition to these nutritive and stimulating functions, GS also inhibits some cartilage-destroying enzymes, such as serine proteases collagenase and phospholipase A_2 (PLA_2), and the generation of cell-damaging superoxide radicals. Thus, GS exerts a mild anti-inflammatory effect by a mechanism of action other than the inhibition of the biosynthesis of prostaglandins, most likely inhibition of proinflammatory effects of the nuclear factor kappa B (NF-κB) pathway.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Glucosamine (sulfate) is primarily used to relieve symptoms, stop disease progression, and stimulate joint cartilage growth in the treatment of osteoarthritis (OA). In this role, GS acts as chondroprotective agent by stopping the pathogenic mechanism of OA, relieving its symptoms, and reducing its progression. Surveys show that it is one of the most widely used nutraceuticals in self-medication practices, especially among the elderly population.[2] Most,[3-12] but not all,[13] published studies, have shown positive effects on both joint pain and joint structure (e.g., joint space narrowing) in patients with OA, particularly of the knee, compared with nonsteroidal anti-inflammatory drugs (NSAIDs) or placebo. In addition to its beneficial activities on cartilage and chondrocytes, glucosamine has generally demonstrated mild anti-inflammatory properties and a favorable pharmacokinetic profile. Until recently, long-term studies on the effectiveness of GS have been lacking.

Historical/Ethnomedicine Precedent

No historical precedents have been reported.

Possible Uses

Cartilage injuries, gonarthritis, kidney stones, low back pain, minor injuries, osteoarthritis (OA), sprains and strains,

temporomandibular joint (TMJ) dysfunction pain and joint noises, wound healing.

Deficiency Symptoms

There are no reports of a glucosamine deficiency, per se, in humans. The issue of sulfate deficiencies may deserve further attention.

Dietary Sources

Tempeh, a fermented soy product, is a food source of glucosamine.[14] However, significant amounts of glucosamine are not a normal constituent of most diets.

Nutrient Preparations Available

Commercially available glucosamine products are available in three forms. Glucosamine sulfate (GS) is the primary form used in clinical settings. However, many products labeled as "glucosamine" contain glucosamine hydrochloride. *N*-acetyl-D-glucosamine (NAG) is a related substance found in joints and connective tissue.

Glucosamine sulfate is the preferred form because of its very high absorption, ease of utilization, immediacy of incorporation into connective tissue matrix, and history of clinical studies. Sulfur is an essential nutrient for joint tissue, where it functions in the stabilization of the connective tissue matrix of cartilage, tendons, and ligaments. In particular, sulfation is an active metabolic process in cartilage, and the sulfate moiety seems to be essential to *sulfation*, an active metabolic process in cartilage. The sulfate moiety also seems to be essential to synovial fluid delivery to articular cartilage as well as improving efficacy of the synovial fluid by strengthening cartilage and aiding GAG synthesis.[3,18] Further, even though it is often used in clinical trials, evidence supporting efficacy of the hydrochloride (HCl) salt of glucosamine is weak and unclear, and its use is rarely recommended by experienced clinicians.[16]

Chitin is a polymer of D-glucosamine with randomly assigned D-glucosamine monomers having a chemically bonded "acetyl" group, giving rise to NAG units. After extraction from the exoskeletons of shrimp and other shellfish, chitin can be chemically modified with hydrochloric acid digestion and deacetylation to yield quite pure D-glucosamine HCl monomers. Combining glucosamine HCl with sulfuric acid yields glucosamine sulfate. Glucosamine sulfate is produced through a co-crystallization step with sodium chloride (NaCl), resulting in a GS-NaCl complex. Alternatively, potassium chloride (KCl) can be used as the co-crystallization agent. Although most clinical trials have focused on the NaCl-stabilized form, the form using KCl as a stabilizer may be preferable for most individuals, given general dietary tendencies toward excess sodium and inadequate potassium intake. However, this issue has not yet been studied in controlled trials. In either form, these mineral salts stabilize GS by decreasing oxidation and moisture absorption.

In contrast, glucosamine HCl is typically granulated to reduce moisture absorption from the air. Salts are usually not necessary for its crystallization, but polyvinylpyrrolidone and corn syrup are often used as binders for granule formation.[17]

Regarding the *N*-acetyl form of glucosamine, researchers have concluded that "glucosamine is a more efficient precursor of macromolecular hexosamine (glycosaminoglycans) than *N*-acetylglucosamine. It is possible that *N*-acetylglucosamine does not penetrate the cell membranes and, as a result, is not available for incorporation into glycoproteins and mucopolysaccharides."[18] Further, clinical trials using NAG in the treatment of osteoarthritis are lacking.

Dosage Forms Available

Capsule, tablet, liquid, powder.

Source Materials for Nutrient Preparations

Supplemental glucosamine is usually derived from the processed exoskeletons of shellfish, such as shrimp, lobster, and crab. Glucosamine may also be synthesized. A novel source of the HCl form is fermented corn-derived glucose, although this may not be a preferred form.

Dosage Range

Adult

Dietary: Not appreciable.
Supplemental/Maintenance: Generally not considered as recommended on a preventive basis, but glucosamine is widely used by individuals with a history of or susceptibility to joint pain or injury.
Pharmacological/Therapeutic: 500 to 2000 mg daily, most often 500 mg three times daily (of GS) orally. Obese individuals may need to increase dosages by 20 mg/kg body weight daily.[19] Anecdotally, many clinicians experienced in treating pain and injuries with nutritional therapies report that doses at two to three times typical levels (i.e., 3000-4500 mg/day) for 3 to 5 days decreases pain and accelerates tissue repair immediately after injury.
Toxic: Glucosamine sulfate is generally considered nontoxic.

Pediatric (<18 Years)

Dietary: Not appreciable.
Supplemental/Maintenance: Not applicable.
Pharmacological/Therapeutic: Ehler-Danlos syndrome, Marfan syndrome.
Toxic: Glucosamine sulfate is generally considered nontoxic.

SAFETY PROFILE

Overview

In the majority of studies, oral GS at standard dosage levels appears to be safe, nontoxic, and well tolerated, with only minor, transient, and reversible adverse effects. Several studies have reported an incidence of adverse effects no greater than among subject receiving placebo.[4,10,20,21] A meta-analysis by the Cochrane Collaboration reported only 16 adverse events requiring withdrawal from investigation, of 1000 patients treated for OA with glucosamine in 16 clinical trials.[22] Injectable and parenteral forms have also generally demonstrated an excellent safety profile. Allergic reactions appear to be rare and when suspected may derive from the shellfish used as source material for most preparations.[23]

Nutrient Adverse Effects

General Adverse Effects

Rarely mild and transient gastrointestinal (GI) effects, including flatulence, abdominal bloating, indigestion, heartburn, nausea, and diarrhea. These symptoms are often reduced by taking GS with a meal.

Adverse Effects among Specific Populations

One study noted that the onset of possible adverse effects was significantly related to preexisting GI disorders and related treatments and to concomitant diuretic treatment.[20]

One unqualified case report of impaired kidney function in a 79-year-old woman with myasthenia gravis, also undergoing corticosteroid and immunosuppressive therapy, resolved with discontinuation of glucosamine.[24]

Pregnancy and Nursing

Although evidence or reports of adverse events associated with glucosamine administration during pregnancy or breastfeeding are lacking, no clinical studies have demonstrated safety in such populations.

Infants and Children

Evidence or reports of adverse events associated with glucosamine intake are lacking, but glucosamine administration is generally inappropriate for most children and should be avoided in those under 2 years of age.

Contraindications

None documented, with the exception of possible (and probably rare) allergic reactivity to shellfish.

Precautions and Warnings

Some individuals with preexisting peptic ulcers or other GI conditions may have increased susceptibility to adverse effects.

INTERACTIONS REVIEW

Strategic Considerations

In general, comprehensive formal drug interaction studies involving glucosamine compounds are lacking. At this time, potential or suspected interactions involving diuretics or oral hypoglycemic agents appear to be discredited, clinically insignificant, or exceptional. A review of the scientific literature indicates that NSAIDs are the drug class most likely to manifest a clinically significant pattern of interaction with GS, and different agents within that class may theoretically produce different outcomes. Although evidence indicates that acetaminophen may obstruct the therapeutic activity of glucosamine, research is warranted to investigate opportunities for possible synergy or additive therapeutic benefit from coadministration with certain NSAIDs, such as ibuprofen.

Over the years, evidence supporting the clinical effectiveness of GS in the treatment of OA has increased in number, depth, and quality. Nevertheless, published clinical guidelines for integrative therapeutics involving glucosamine in the treatment of OA remain nascent and out of step with the clinical practices that have matured based on anecdotes, outcomes, and collective experience. At this point, the position of glucosamine as a potential first-line agent for repair of damaged or degenerating joint cartilage is reaching consensus level, at minimum for patients with knee OA who have mild to moderate pain. Ongoing and future studies of structure-modifying anti-OA drugs such as GS and chondroitin sulfate (CS) present the opportunity for further confirming the efficacy of these agents and clarifying appropriate therapeutic protocols customized to meet the needs of individuals and their variable life stages, personal history, genetic predispositions, diagnoses, and prognoses.

More fundamentally, the challenge of integrative medical care for OA will be to investigate, analyze, and synthesize the therapeutic strengths and opportunities presented by the range of treatment modalities. The therapeutic approach to integrative care of OA cannot rely solely on natural substances such as glucosamine alone or, for that matter, on any exclusively pharmacological approach. Other nutritional and botanical approaches, such as *S*-adenosylmethionine (SAMe), vitamin E, vitamin B_3 (niacinamide), bromelain, green-lipped mussel *(Perna canaliculus)*, methylsulfonylmethane (MSM), cetyl myristoleate (CMO), topical capsaicin, turmeric *(Curcuma longa)*, ginger *(Zingiber officinale)*, devil's claw *(Harpagophytum procumbens)*, boswellia *(Boswellia serrata)*, and cat's claw *(Uncaria tomentosa)*, are beginning to be studied in well-designed clinical trials, as are interventions such as aerobic exercise, quadriceps exercises, and footwear modification. Although the role of NSAIDs continues to undergo reformation in light of its limitations and adverse effects, new cyclooxygenase-2 (COX-2) inhibitors may have a role in situational symptom management in patients for whom simple analgesia is inadequate. Intra-articular hyaluronate injections may also have a limited role. Furthermore, the patient population appears receptive to medical and lifestyle interventions, such as weight reduction, yoga, tai qi, massage, acupuncture, and manipulative therapies, which are often beyond the realm of the average physician's training and experience, but which may be able to play an important role in restoring mobility and enhancing vitality within the context of an integrative therapeutic strategy.

Gottlieb[25] calls for a fundamental reevaluation of the medical view of OA and presents a perspective that remains challenging in its comprehensive approach in his 1997 review article, "Conservative management of spinal osteoarthritis with glucosamine sulfate and chiropractic treatment":

> The rationales for using NSAIDs in the treatment of osteoarthritis is controversial and openly contested. Given the detrimental effects of NSAIDs on joints and other organs, their use should be discouraged and their classification as a first choice conservative treatment should be abolished. A truly effective and conservative approach to the treatment of osteoarthritis should include chiropractic manipulation [or other forms of joint mobilization and manipulation], essential nutrient supplementation, exogenous administration of glucosamine sulfate and rehabilitative stretches and exercises to maintain joint function. Because there is no correlation between pain levels and the extent of degeneration detected by radiographic or physical examination, conservative treatment should be initiated and sustained based on functional, objective findings and not strictly on how the patient feels. The use of NSAIDs should be limited to the treatment of gross inflammation and analgesics should only be used in the short-term when absolutely necessary for pain palliation. The present conservative approach could lead not only to a better quality of life but also to the saving of health care dollars by reducing the iatrogenic morbidity and mortality associated with NSAID use.

Thus, emerging approaches to treatment of OA may be prime ground for exploring the broad value, in terms of quality of life and meaningful outcomes standards, for multidisciplinary collaboration and integrative therapeutics.

NUTRIENT-DRUG INTERACTIONS

Acetaminophen, Ibuprofen, and Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

Acetaminophen (APAP, paracetamol; Tylenol); combination drugs: acetaminophen and codeine (Capital and Codeine; Phenaphen with Codeine; Tylenol with Codeine); acetaminophen and hydrocodone (Anexsia, Anodynos-DHC, Co-Gesic,

Dolacet, DuoCet, Hydrocet, Hydrogesic, Hy-Phen, Lorcet 10/650, Lorcet-HD, Lorcet Plus, Lortab, Margesic H, Medipain 5, Norco, Stagesic, T-Gesic, Vicodin, Vicodin ES, Vicodin HP, Zydone); acetaminophen and oxycodone (Endocet, Percocet 2.5/325, Percocet 5/325, Percocet 7.5/500, Percocet 10/650, Roxicet 5/500, Roxilox, Tylox); acetaminophen and pentazocine (Talacen); acetaminophen and propoxyphene (Darvocet-N, Darvocet-N 100, Pronap-100, Propacet 100, Propoxacet-N, Wygesic); acetaminophen, butalbital, and caffeine (Fiorcet).

COX-1 inhibitors (NSAIDs): Diclofenac (Cataflam, Voltaren), combination drug: diclofenac and misoprostol (Arthrotec), diflunisal (Dolobid), etodolac (Lodine), fenoprofen (Dalfon), furbiprofen (Ansaid), ibuprofen (Advil, Excedrin IB, Motrin, Motrin IB, Nuprin, Pedia Care Fever Drops, Provel, Rufen; combination drug: hydrocodone and ibuprofen (Reprexain, Vicoprofen), indomethacin (indometacin; Indocin, Indocin-SR), ketoprofen (Orudis, Oruvail), ketorolac (Acular ophthalmic, Toradol), meclofenamate (Meclomen), mefenamic acid (Ponstel), meloxicam (Mobic), nabumetone (Relafen), naproxen (Aleve, Anaprox, Naprosyn), oxaprozin (Daypro), piroxicam (Feldene), salsalate (salicylic acid; Amigesic, Disalcid, Marthritic, Mono Gesic, Salflex, Salsitab), sulindac (Clinoril), tolmetin (Tolectin).

COX-2 inhibitor (NSAID): Celecoxib (Celebrex).

Effect and Mechanism of Action

Even when they temporarily relieve pain and reduce inflammation, NSAIDs may accelerate the progression of OA and similar connective tissue trauma, joint degeneration, or related disorders by promoting cartilage destruction and interfering with cartilage repair. However, this effect may vary among the different agents in this drug class. Glucosamine sulfate intake can significantly increase serum sulfate concentrations, required for GAG synthesis, and thereby elevate synovial fluid sulfate concentrations and enable proteoglycan sulfation. Acetaminophen metabolism involves sulfation and thus consumes the sulfate provided by GS and interferes with the therapeutic action of the nutrient.[1] Other NSAIDs appear to interact with GS to produce variable metabolic effects on the synovial environment and cartilage repair.

Research

Numerous in vivo, animal, and human studies suggest that many NSAIDs exert deleterious effects on synthesis of vasodilator prostaglandins, joint perfusion, chondrocyte and proteoglycan metabolism, cartilage synthesis, and organization in articular cartilage, especially influencing the course of OA.[26-32] Zupanets et al.[33] first investigated combining glucosamine and NSAIDs to determine if any resultant additive or synergistic effect might enable reduction of dosage levels necessary to obtain anti-inflammatory activity and thereby reduce adverse effects associated with these agents. They found that lower doses of voltaren, indomethacin, and piroxicam could be used in conjunction with glucosamine to reduce experimentally induced inflammation in mice and attributed these phenomena to a "diverse influence of aminosugar on the anti-inflammatory effect of nonsteroidal anti-inflammatory drugs." In unrelated but potentially significant research, Shikhman et al.[34] found that adding either glucosamine or NAG to human cartilage in vitro reduced inflammatory changes and gene expression induced by two different cytokines (interleukin 1β and tumor necrosis factor). This focus on the glucosamine led to, or at least paralleled, a focus on the respective roles and relative efficacy of the sulfate and hydrochloride forms and the mechanisms of NSAIDs' apparent interference with healthy cartilage nutriture and repair.

In a study of the effect of glucosamine hydrochloride's effect on pain associated with OA of the knee, Houpt et al.[16] reported minimal efficacy in individuals concurrently taking up to 4000 mg acetaminophen daily. Interestingly, this and the GAIT studies are the primary published clinical trials involving glucosamine that are cited as lacking a beneficial outcome. Seeking to determine the relative importance of the sulfur component of GS, Hoffer et al.[1] and observed a significant increase in serum sulfate in subjects who received GS, versus sodium sulfate, after administering both compounds to healthy subjects, despite the elemental sulfate dose being doubled. The authors interpreted this increase in availability of sulfur compounds as critical to the delivery of critical nutrients to the synovium, which serves as the primary nutrient reservoir for cartilage that lacks significant direct blood supply. In particular, synovial fluid free sulfate appears to be essential to proteoglycan sulfation. These observations supported the researchers' hypothesis that sulfate, rather than glucosamine, was the critical component of GS in its action on cartilage formation. In the second phase of this experiment, serum sulfate levels fell in those administered both acetaminophen and GS. Given that acetaminophen metabolism involves sulfation, these authors suggested that the drug consumed the sulfate provided by GS and would presumably blunt its nutritive effect on synovial fluid and therapeutic efficacy. Finally, they measured the serum and knee synovial fluid sulfate concentrations in OA patients and found virtually identical concentrations in both compartments, thus confirming the interrelationship of nutrient levels, particularly sulfate, between blood and synovial fluid.[1] Thus, in retrospect, questions arise as to whether the acetaminophen in the Houpt study may have interfered with the subjects' obtaining the full measure of glucosamine's potential benefit and whether acetaminophen might interfere with the activity of glucosamine compounds by some mechanism other than affecting sulfation. Nevertheless, even in this study, as the authors noted: "After the end of the 8 week open label trial, 77% of the subjects were still taking glucosamine, although now obliged to pay for commercially available products."[16]

Subsequently, using a mouse model, Tallarida et al.[35] reported that commercial GS "administered as the sole agent (up to 500 mg/Kg, p.o.) was inactive in the mouse abdominal irritant test, but that certain combinations of glucosamine with nonopioid analgesics at the oral doses and ratios tested resulted in a synergistic (ibuprofen and ketoprofen), additive (diclofenac, indomethacin, naproxen, and piroxicam), or subadditive (aspirin and acetaminophen) antinociceptive interaction." Examining specific fixed ratios of glucosamine and certain NSAIDs, they found that combinations containing racemic ibuprofen and glucosamine in greater than 1:1 ratio

(glucosamine/ibuprofen) were synergistic in the test and that combinations of 2:1 and 9:1 yielded plasma levels of ibuprofen that were no different from administration of ibuprofen alone. These authors suggested that their findings supported further research into synergistic coadministration of GS and certain NSAIDs to enhance pain relief while reducing adverse effects usually associated with higher doses of NSAIDs.[35] Despite the continued use of glucosamine hydrochloride in major clinical trials, their concluding declaration that these findings were "being pursued in clinical trials" provides encouragement that important initial steps are being taken toward clarifying these significant findings and critically exploring such integrative therapeutic innovations.

Clinical research into the efficacy of glucosamine in the treatment of joint pain, inflammation, and degeneration has evolved to the point where opportunities for integrative therapeutic combinations are now ripe for systematic investigation. Although glucosamine and NSAIDs might appear superficially to contribute to the same therapeutic goals—relief of joint pain and degeneration—the evidence indicates that their respective mechanisms of action, character of effect, and role in strategic clinical management may result in either cooperative or antagonist influences and divergent outcomes, depending at least in part on the particular NSAID employed. One important factor in whether glucosamine (particularly GS) and individual NSAIDs potentiate or interfere with one another depends on the role of sulfation in each particular drug's metabolism. Research is still preliminary and large, well-designed clinical trials are clearly warranted. However, the findings thus far further suggest that those engaged in research design for studies of glucosamine's effect on OA or other forms of joint pain, as well as clinicians, should not allow subjects to use acetaminophen as a "rescue" drug, as has sometimes occurred in the past. Thus, heavier users of acetaminophen might derive less benefit from GS by diverting sulfate for drug metabolism, because acetaminophen is metabolized by multiple pathways, including sulfation.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

In light of the accumulated and evolving evidence, concomitant use of glucosamine and particular NSAIDs appears to be a potentially valuable therapeutic option in the treatment of conditions for which both agents are typically used. However, based on both animal and human research, discrimination in selecting the most efficacious NSAID appears to be critical. Evidence suggests that coadministration of ibuprofen with GS may provide a synergistic therapeutic effect and that acetaminophen should be avoided. Such approaches, while novel and exploratory, appear to offer enhanced combined efficacy at minimal risk and cost and, because of the ability to reduce NSAID dosage levels, a likelihood of reduced risk of adverse effects. A reasonable option where the activity of an NSAID seems indicated might be combining the standard dosage of GS (500 mg) with ibuprofen (200 mg), three times daily, with phasing out of the ibuprofen to an as-needed basis when clinically improved. This long-term clinical strategy thus shifts from symptom management to maintenance, with emphasis on tissue strengthening and maximal restoration of healthy function.

Oral Hypoglycemic Agents and Insulin

Buformin (Andromaco Gliporal, Buformina), chlorpropamide (Diabinese), glimepiride (Amaryl), glipizide (Glucotrol; Glucotrol XL), glyburide (glibenclamide; Diabeta, Glynase, Glynase Prestab, Micronase, Pres Tab), insulin (animal-source insulin: Iletin, human analog insulin: Humanlog; human insulin: Humulin, Novolin, NovoRapid, Oralin), metformin (Dianben, Glucophage, Glucophage XR); combination drugs: glipizide and metformin (Metaglip), glyburide and metformin (Glucovance); tolazamide (Tolinase), phenformin (Debeone, Fenformin), tolbutamide (Orinase, Tol-Tab).

Interaction Type and Significance

Probability: **5. Improbable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

It has been hypothesized that because of the chemical similarity between glucosamine-6-phosphate and glucose-6-phosphate, glucosamine could activate the hexosamine pathway and induce inhibition of liver glucokinase and thereby cause clinically significant changes in glucose metabolism and potentially contribute to the development of insulin resistance.[36-45] If proven in humans, such effects might theoretically mean that glucosamine administration could decrease the effectiveness of insulin or other oral hypoglycemic agents used in the management of diabetes mellitus.

Research

Several preliminary animal studies suggested that glucosamine, often administered in relatively high dosage levels by continuous intravenous (IV) infusion, could accelerate the hexosamine pathway and lead to peripheral insulin resistance and decreased insulin secretion. Giaccari et al.[38] found that high-dose glucosamine infusions significantly (40%-50%) impaired glucose-induced insulin secretion (both first and second phases), greatly reduced muscle glucose 6-phosphate concentration and reduced insulin stimulation of both glycolysis and glycogen synthesis in rats. Rossetti et al.[37] found that in vivo glucosamine infusion induces insulin resistance in normoglycemic but not in hyperglycemic rats. Barzilai et al.[39] observed that glucosamine induced inhibition of liver glucokinase, which in turn impaired the ability of hyperglycemia to suppress endogenous glucose production. Virkamaki et al.[40] reported that activation of the hexosamine pathway by glucosamine in vivo induced insulin resistance and increased risk of glucose toxicity in skeletal muscle and other insulin-sensitive tissues. Collectively, these and other findings from animal studies suggested that exogenous glucosamine might alter glucose metabolism to such an extent as to aggravate insulin resistance and potentially adversely interact with insulin and other medications prescribed for glucose control. However, the speculative nature of these findings was generally acknowledged, especially in light of dosage levels, based on weight, that were beyond the range of normal therapeutic dosages and usually significantly higher than might ever be obtained in humans through oral administration.[46,47]

Human trials that have examined the effects of glucosamine intake, in various forms, on glucose metabolism have generally found evidence lacking of adverse effects on glycemic control. Noack et al.[5] found that glucose metabolism is not impaired by short-term GS intake, 500 mg three times daily, in a general population of 252 patients being treated for knee OA. In this multicenter, randomized, placebo-controlled, double-blind, parallel-group study, fasting plasma glucose levels were not modified over a 4-week treatment with GS or placebo,[5] nor were they modified in the small subset of subjects the authors thought could be defined as diabetic, "in whom mean plasma glucose concentrations fell both in the nine patients on glucosamine and the 14 given placebo."[46] In a large, 3-year,

placebo-controlled OA study, researchers observed only a tendency for fasting blood glucose to decrease with glucosamine, compared with subjects receiving placebo for whom it remained stable. Although there were few diabetic patients in this long-term study, those with high baseline glucose concentrations, when analyzed separately, showed a tendency for similar results, with a fall in plasma glucose among those taking glucosamine.[48] In related research, Pouwels et al.[49] determined that short-term glucosamine infusion does not affect insulin sensitivity in healthy human subjects (n=18); thus, their findings did not support involvement of the hexosamine pathway in the regulation of insulin sensitivity in humans. In a focused and definitive study, the first placebo-controlled, double-blind trial of its kind, Scroggie et al.[47] evaluated the effects of glucosamine hydrochloride (1500 mg/day), together with chondroitin sulfate (1200 mg/day), versus placebo, for 90 days on glycemic control in a group of 34 mostly elderly patients with type 2 diabetes. They reported that mean hemoglobin A_{1c} levels, a marker for long-term blood-glucose control, remained relatively stable in the glucosamine group and decreased in the placebo group. In a double-blind clinical trial involving 19 healthy adults, Tannis et al.[50] administered 1500 mg GS or placebo daily for 12 weeks to test for glucosamine-induced glucose intolerance. Three-hour oral glucose tolerance tests were performed before the start of administration, at 6 weeks, and at the completion of administration. These researchers found no significant differences between fasted levels of serum insulin or blood glucose. They observed that GS treatment did not alter serum insulin or plasma glucose during the glucose tolerance tests, and that glycosylated hemoglobin (HbA_{1c}) measurements at the three time points showed no significant change over time, within or between treatments, ages, or gender. Collectively, these human trials provide significant evidence that oral glucosamine, at recommended dosage levels, does not result in clinically significant alterations in glucose metabolism in patients with type 2 diabetes mellitus and is unlikely to interact adversely with insulin or other oral hypoglycemic agents.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Given its favorable risk/benefit ratio, especially compared with NSAIDs, GS therapy offers an attractive option to both patients and physicians in the treatment of appropriate conditions. Thus, Scroggie et al.[47] concluded: "Since patients with diabetes are at risk for toxic effects from some of the current treatments for osteoarthritis (NSAIDs in particular), glucosamine may provide a safe alternative treatment for these patients." Nevertheless, introduction of new medications or significant alterations in existing prescriptions can disrupt glycemic control in patients being treated for type 2 diabetes. Thus far, the weight and direction of evidence indicates that GS, or related forms, does not pose a significant risk of disrupting clinical management of such patients. Even so, it would be judicious to monitor short-term and long-term markers of blood glucose control closely in such patients whenever there are significant changes in treatment of glucose-related or other conditions.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Diuretics

Potassium-Sparing Diuretics: Amiloride (Midamor), spironolactone (Aldactone), triamterene (Dyrenium); combination drugs: amiloride and hydrochlorothiazide (Moduretic); spironolactone and hydrochlorothiazide (Aldactazide); triamterene and hydrochlorothiazide (Dyazide, Maxzide).

Loop Diuretics: Bumetanide (Bumex), ethacrynic acid (Edecrin), furosemide (Lasix), torsemide (Demadex).

Thiazide Diuretics: Bendroflumethiazide (bendrofluazide; Naturetin); combination drug: bendrofluazide and propranolol (Inderex); benzthiazide (Exna), chlorothiazide (Diuril), chlorthalidone (Hygroton), cyclopenthiazide (Navidrex); combination drug: cyclopenthiazide and oxprenolol hydrochloride (Trasidrex); hydrochlorothiazide (Aquazide, Esidrix, Ezide, Hydrocot, HydroDiuril, Microzide, Oretic); combination drugs: hydrochlorothiazide and amiloride (Moduretic); hydrochlorothiazide and captopril (Acezide, Capto-Co, Captozide, Co-Zidocapt); hydrochlorothiazide and enalapril (Vaseretic); hydrochlorothiazide and lisinopril (Prinzide, Zestoretic); hydrochlorothiazide and losartan (Hyzaar); hydrochlorothiazide and metoprolol (Lopressor HCT); hydrochlorothiazide and spironolactone (Aldactazide); hydrochlorothiazide and triamterene (Dyazide, Maxzide); hydroflumethiazide (Diucardin), methyclothiazide (Enduron), metolazone (Zaroxolyn, Mykrox), polythiazide (Renese), quinethazone (Hydromox), trichlormethiazide (Naqua).

Thiazide-like Diuretics: Indapamide (Lozol).

Glucosamine sulfate (GS) is stabilized with a mineral salt and consequently contains relatively high amounts of potassium chloride (KCl) or sodium chloride (NaCl). The action of diuretics on potassium may result in increased potassium levels or decreased effective levels of GS. Furthermore, individuals taking diuretics for hypertension, or otherwise on a sodium-restricted diet, may be adversely affected by the elevated sodium intake resulting from a glucosamine preparation stabilized with sodium. Likewise, individuals on a potassium-restricted diet may experience adverse effects from concomitant use of a diuretic and glucosamine stabilized with potassium. For example, in a product containing 300 mg GS per one tablet serving, a 12% potassium level (12%-13.5%) for source GS (potassium salt) would contain 36 mg potassium (36-41 mg). The proportion and amount of the sodium content in a sodium-based glucosamine salt would be comparable.[51] In other words, approximately 200 mg sodium or potassium, respectively, are included in a daily dose of 1500 mg GS.

Although the pharmacological rationale for this potential interaction between diuretics and glucosamine sulfate appears to be reasonable and well founded, evidence as to its clinical significance and any pattern of occurrence remains inadequate. In concluding their study of oral GS in the management of arthrosis, Tapadinhas et al.[20] noted that glucosamine administration was generally well tolerated, but adverse effects were significantly related to concomitant diuretic treatment, as well as to preexisting GI disorders and related treatments.

Physicians prescribing diuretics are advised to ask patients about their use of glucosamine (and other supplements) and to monitor blood pressure regularly and measure potassium levels as appropriate. Some individuals taking diuretics may need to take higher doses of glucosamine to obtain the full therapeutic effect, usually 20 mg/kg daily.[19] Daily fruit or other concomitant potassium may also be appropriate for individual on long-term therapy with potassium-depleting diuretics.

NUTRIENT-NUTRIENT INTERACTIONS

Bromelain

Glucosamine sulfate and bromelain are often used together in clinical practice for the treatment of joint pain and

inflammation of traumatic or degenerative origin. The mechanism and efficacy of any additive or synergistic interaction remain to be investigated in well-designed clinical trials. However, the rationale of supportive activity appears reasonable, especially in light of bromelain's more immediate anti-inflammatory effects complementing glucosamine's relatively gradual, long-term, and primarily nutritive action.

Chondroitin Sulfate

See also previous section on NSAIDs.

Numerous animal and human trials have used chondroitin sulfate (CS) together with glucosamine compounds, particularly GS, and most have found the combination more effective than either agent alone, particularly in the treatment of osteoarthritis (OA).[12,22,47,52-59] Nevertheless, in the 4-year Glucosamine/chondroitin Arthritis Intervention Trial (GAIT) involving almost 1600 participants with documented knee OA, Clegg et al.[59] found that glucosamine hydrochloride (500 mg three times daily), CS (400 mg three times daily), or the combination for 24 weeks did not provide statistically significant relief (defined as a decrease in pain of at least 20%) from OA-associated pain among all subjects, compared with placebo and celecoxib (200 mg daily) as positive control. However, an analysis of the subgroup with initial moderate to severe pain (i.e., excluding those with mild pain) revealed relief with the combined nutrients at statistically significant levels compared with placebo (79.2% vs. 54.3%) or celecoxib (69.4%). Also, 60% of all subjects administered placebo reported 20% or greater pain reduction; this high response rate in the placebo group may have obscured a therapeutic response in subjects administered the glucosamine and/or CS, especially among subjects with initial mild pain. As with many similar trials, participants were allowed to use up to 4000 mg acetaminophen daily for pain, except for the 24 hours before assessment, further confounding the data and possibly adversely affecting therapeutic response. Notably, however, resort to such "rescue" acetaminophen was relatively low, overall averaging fewer than two 500-mg tablets daily.[60,61] Interestingly, in most news accounts (both professional and lay), and even in the published abstract, the terms "glucosamine" and "glucosamine and chondroitin sulfate" are used, and only in the "Methods" section of the full text does the use of "glucosamine hydrochloride" (vs. glucosamine sulfate) become evident. The pivotal clinical issue of disease progression (vs. pain relief), including joint function and regeneration, was not addressed in this study. Such elements of pathophysiology are central to the therapeutic strategy of nutritional interventions such as the sulfate compounds and is illuminated by research demonstrating that meniscal pathology increases the risk of cartilage loss in patients with symptomatic knee OA.[62]

Chondroitin sulfate tends to be more chondroprotective than regenerative and, as a much larger molecule (compared to GS), may be difficult to absorb. Concern has also been raised that CS may also interfere with GS absorption. Further research to explore systematically the nature of the interaction and its clinical implications is warranted.

Manganese

Manganese is an essential cofactor in bone and cartilage formation and may enhance glucosamine utilization within chondrocytes. Concomitant administration of glucosamine and manganese may produce increased therapeutic effects.[53]

Methylsulfonylmethane

Methylsulfonylmethane (MSM), the isoxidized form of dimethyl sulfoxide (DSMO), is often used as a natural analgesic and anti-inflammatory agent. MSM and glucosamine are frequently coadministered in the treatment of musculoskeletal injuries, OA, and similar conditions. In a 12-week, randomized, double-blind, parallel, placebo-controlled trial involving 118 subjects, Usha and Naidu[63] demonstrated that oral "glucosamine" (500 mg three times daily, sulfate form inferred) and MSM (500 mg three times daily), individually and in combination, significantly improved signs and symptoms of OA compared with placebo. These researchers noted that the "onset of analgesic and anti-inflammatory activity was found to be more rapid with the combination" and concluded that together these agents provide "better and more rapid improvement in patients with osteoarthritis." Further research is warranted. In the meantime, MSM, alone and with glucosamine, is generally well tolerated and considered safe at usual dosage levels; it also lacks the characteristic odor associated with DMSO.

Oligomeric Proanthocyanidins

Oligomeric proanthocyanidins (OPCs), most widely provided by grape seed and pine bark extracts, bind to collagen and elastin and have been shown to protect these tissues from collagenases and elastinases (which are locally generated by the inflammatory cascade). Thus, OPCs may also synergize with the chondroprotective and nutritive effects of glucosamine sulfate.[64] Researchers have demonstrated that the Pycnogenol brand of pine bark extract can prevent cramps and muscular pain "in normal subjects, venous patients, athletes, claudicants and in diabetic microangiopathy."[65]

Omega-3 Fatty Acids, Especially Fish Oils, Eicosapentaenoic Acid, and Docosahexanoic Acid

The combination of glucosamine and fish oil, containing eicosapentaenoic acid (EPA) and docosahexanoic acid (DHA), may have an additive effect in the treatment of psoriasis,[66] and possibly other inflammatory conditions.

Vitamin C

Vitamin C is an essential component of collagen and the extracellular matrix of cartilage. Concomitant administration of glucosamine and vitamin C may produce increased therapeutic effects.

The 66 citations for this monograph, as well as additional reference literature, are located under Glucosamine Sulfate on the CD at the back of the book.

Inositol

Nutrient Name: Inositol.
Synonyms: *cis*-1,2,3,5-*trans*-4,6-cyclohexanehexol, cyclohexanehexol, hexahydroxycyclohexane, inositol monophosphate, mouse antialopecia factor, myo-inositol, vitamin B_8.
Related Substances: Inositol hexaphosphate, IP6, phytic acid; D-chiro-inositol; inositol hexaniacinate, inositol niacinate, inositol nicotinate (see Vitamin B_3 monograph).

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Lithium ☼/⊕	Lithium inhibits inositol monophosphatase and depletes brain stores of inositol. Coadministration may reduce adverse effects associated with chronic lithium therapy, especially psoriasis and polydipsia-polyuria, without reducing treatment efficacy. Long-term, well-designed clinical trials are warranted.	Coadminister. Monitor.

NUTRIENT DESCRIPTION

Chemistry and Forms

First recognized as an essential nutrient in 1940, inositol is a sugar-like, water-soluble substance member of the B-vitamin complex. The nine isomers of inositol are ubiquitous, cyclic carbohydrates with a basic 6-carbon ring structure. Three forms of inositol occur in nature: phytic acid, free *myo*-inositol, and inositol-containing phospholipids. Phytic acid, the hexaphosphate ester of inositol, is present in the leaves and seeds of most plants. In mammal tissues, inositol appears as phosphorylated derivatives, various phosphoinositides, and in its free form. The highest concentrations of inositol are in the heart and brain, with free *myo*-inositol predominantly found in the brain and kidney, and phospholipid inositol (phosphatidylinositol) concentrated in liver, pancreas, skeletal muscle, and cardiac muscle.

Physiology and Function

Although the distribution of inositol within the human body has long been known, its functions and mechanisms of action have yet to be fully elucidated.

Inositol production occurs through three known pathways. Dietary sources primarily enter the system as phytate or phytic acid (inositol hexaphosphate, or IP6) in plant foods, which is converted in the intestinal tract through the action of endogenous bacterial flora. However, oral intake of inositol is considered a minor pathway. The majority of inositol is produced, as inositol monophosphate, via a receptor-mediated salvage system and from glucose-6-phosphate; these two pathways are regulated by polyphosphate-1-phosphomonoesterase, a lithium-sensitive enzyme.

Inositol plays key roles in lipid transport, hepatic fat metabolism and cell membrane function, nerve transmission, and neurotransmitter activity. Along with choline (tetramethylglycine), methionine and betaine (trimethylglycine), inositol is considered a member of the group of compounds called *lipotropics*, which are closely involved in lipid metabolism. As an essential component of phospholipids, phosphatidylinositol participates in regulating the function of cell membranes, where it is particularly important in mediating cellular responses to external stimuli and/or nerve transmission. Inositol with various numbers of bound phosphate groups are also widely involved in cell-signaling processes.

Phosphatidylinositol (PI) mediates the activity of numerous membrane enzymes through interactions with specific proteins. The PI cycle is a second-messenger system integral to the function of several noradrenergic, serotonergic, and cholinergic receptors. Thus, PI participates in the action of serotonin; low cerebrospinal fluid (CSF) levels of inositol have been observed in individuals diagnosed with depression. Phosphatidylinositol also facilitates the synthesis of arachidonic acid.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Inositol has been used in clinical trials with several central nervous system (CNS) disorders, such as Alzheimer's disease, binge eating, bulimia, depression, obsessive-compulsive disorder (OCD), and panic disorder, as well as concurrently with lithium treatment of bipolar disorder.

Historical/Ethnomedicine Precedent

Inositol has not been used historically as an isolated nutrient.

Possible Uses

Alzheimer's disease, bulimia, depression, diabetes mellitus, diabetic neuropathy, lithium-related psoriasis, OCD, panic disorder, pediatric respiratory depression syndrome, premenstrual dysphoric disorder, trichotillomania.

Deficiency Symptoms

Consensus is lacking on specific signs and symptoms of inositol deficiency. Deficiency is considered unlikely in most individuals because of its widespread occurrence in foods. However, loss of intestinal flora necessary for conversion of such plant sources to inositol could reduce inositol levels.

Individuals with diabetes have increased inositol excretion, whereas those with depression exhibit significantly lower-than-normal CSF levels of inositol.

Dietary Sources

Nuts, beans, seeds, whole grains (especially wheat and wheat bran), cantaloupe, and citrus fruits (especially oranges) are

excellent plant sources of inositol in the form of phytate or phytic acid (inositol hexaphosphate, IP6). Organ meats are the richest animal sources.

Dosage Forms Available

Capsule, powder, tablet.

Source Materials for Nutrient Preparations

The dominant commercial process for producing *myo*-inositol is purification of phytic acid (IP6) from grain such as corn, and then dephosphorylating it with proprietary enzymes.

Dosage Range

Adult

Dietary: No dietary or nutritional requirement for inositol has been established. Average adult intake in the United States has been estimated at 1000 mg daily as phytate or phytic acid.
Supplemental/Maintenance: 100 to 1000 mg per day. Inositol usually is not recommended for general nutritional supplementation. Doses found in multivitamins, if at all present, are generally insufficient to exert any clinically significant effect.
Pharmacological/Therapeutic: 100 to 1000 mg per day, usually 250 to 500 mg twice daily; 12 to 18 g per day have been used in clinical trials investigating treatment of anxiety, depression, and obsessive-compulsive disorder. Palatnik et al.[1] (2001) found that 18 g daily was well tolerated with minimal adverse effects.
Toxic: No toxic dose level for inositol has been reported. Large amounts (>3 g), if quickly ingested, can have a laxative effect, similar to that of sugar alcohols (e.g., maltitol, xylitol).

Pediatric (<18 Years)

Dietary: No minimal dietary requirement for children has been established.
Supplemental/Maintenance: Inositol is not currently recommended for children.
Pharmacological/Therapeutic: Specific treatment recommendations have not established.
Toxic: No toxic dosage level for inositol has been established specifically for infants and children.

Laboratory Values

Blood and CSF inositol levels can be done in research laboratories, but are not in clinical use.

SAFETY PROFILE

Overview

No toxic effects reported or observed, even though some clinical trials have used a therapeutic dosage that equals about 18 times the average dietary intake. Gastrointestinal effects such as nausea and diarrhea are occasionally reported with larger doses. Because of the hypothetical possibility that inositol may exacerbate hypomanic or manic symptoms in those with bipolar disorder, these individuals should use larger amounts (>1 g) of inositol with caution and under medical supervision. There have been no long-term safety studies to confirm the lack of adverse effects with chronic administration.

Nutrient Adverse Effects

General Adverse Effects

No general adverse effects from inositol have been confirmed in the scientific literature.

Pregnancy and Nursing

The use of inositol in pregnant women remains controversial because of possible effects on oxytocin and uterine contractions.

Infants and Children

Evidence is lacking in the scientific literature to suggest or confirm any adverse effects related to fetal development during pregnancy or to breast-fed infants and associated with inositol administration. Caution still is advised.

Contraindications

Attention deficit–hyperactivity disorder (ADHD), chronic renal failure, schizophrenia, pregnancy.

Following up on research by Levine et al.[2] that found a lack of efficacy with the use of inositol in the treatment of schizophrenia, research by Jope et al.[3] and others indicates that schizophrenia involves elevated activity of the phosphoinositol signaling system; thereby suggesting that inositol administration may be contraindicated.

In a double-blind, crossover study involving 11 children with ADHD, Levine et al.[4] found that inositol administration was associated with a trend toward the aggravation of the disorder.

Preliminary, but pharmacologically plausible, evidence suggests inositol may trigger manic episodes in individuals diagnosed with bipolar disorder.[5] These individuals should use *myo*-inositol with caution and only under medical supervision because of the theoretical possibility of exacerbating hypomanic or manic symptoms.

The issue of inositol administration during pregnancy raises complex and as-yet unresolved issues. Animal experiments indicate that inositol may significantly reduce the incidence of embryonic neural tube defects, including those resistant to folate alone.[6,7] However, as reported by Phaneuf et al.,[8] oxytocin's clinical effectiveness is caused by the activation of phospholipase C to produce inositol-1,4,5-triphosphate, which in turn releases calcium from intracellular stores and stimulates uterine contractions. Consequently, inositol may stimulate uterine contractions. Using a rodent model, Chien et al.[9] also observed dose-related myometrial contractions related to activation of the phosphatidylinositol signaling system by calcium agonists. Further research is warranted; inositol administration during pregnancy should be avoided out of prudence until safety factors are clarified and confirmed.

Precautions and Warnings

It has been suggested that exogenous inositol may stimulate uterine contractions, but evidence from human research is lacking to demonstrate such an adverse effect.[10] Thus, the usefulness of inositol in preventing neural tube defects (as supported by animal experiments) is limited.

INTERACTIONS REVIEW

Strategic Considerations

Although much is known about the physiological roles of *myo*-inositol, therapeutic strategies using inositol remain largely

within the realm of clinical trials, clinical experience, anecdote, and conjecture. *Myo*-inositol may have antidepressant and anti-anxiety activity, but the mechanism of action has yet to be fully elucidated. Furthermore, no clinically available means exist to assess inositol status, or even normal ranges of nutrient concentration in blood. Data are available on inositol levels in CSF, but routine lumbar punctures for determining inositol concentration are impractical. Dietary intake typically supplies about a gram per day but relies on bowel flora to dephosphorylate it, which is not necessarily a valid assumption given the disproportionate ratio of antibiotic/probiotic use among most patients. Endogenous synthesis from glucose is the major source, but this depends on assumptions as to how intact that pathway is in any given individual. Inositol synthesis and regulation also involve salvage-recirculating pathways known to be inhibited by lithium and perhaps other substances. Inositol and its phosphates are ubiquitous in cell-signaling pathways, and its phosphatides in membrane signaling.

Experienced clinicians report that a major proportion of individuals diagnosed with depression, anxiety/panic disorder, and OCD appear to improve when given prescribed inositol in multigram quantities per day. Unfortunately, the CSF level does not appear to predict who will and will not respond, even though it is known that inositol levels in CSF are lower in depressed patients than in euthymic individuals. This differential response may be influenced or determined by cofactors that are adequate in some individuals and low in others. One relevant action of inositol may derive from its apparent ability to reverse desensitization of serotonin receptors. As with other antidepressant agents, the logical course, treating patients with mild symptoms of depression, anxiety, and/or obsessive-compulsive thoughts/behavior, is to start with a low dose (1 g/day) and gradually increase to maximum dose (animals models have used 1.2 g/kg with no adverse effects).

NUTRIENT-DRUG INTERACTIONS

Lithium Carbonate

Lithium carbonate (Camcolit, Carbolith, Duralith, Eskalith, Li-Liquid, Liskonum, Litarex, Lithane, Lithobid, Lithonate, Lithotabs, PMS-Lithium, Priadel).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action

Lithium's activity in bipolar disease may involve depletion of brain stores of inositol through inhibition of inositol monophosphatase, the enzyme that returns inositol monophosphate back to *myo*-inositol.[11] Inositol can reverse or mitigate adverse effects of lithium therapy, such as psoriasis and polyuria-polydipsia syndrome and lithium-pilocarpine–induced seizures.[12] However, concern has been raised that such concomitant administration might interfere with the therapeutic effects of lithium by increasing the concentration of inositol, thereby causing a return of manic or depressive symptoms.

Research

In a 6-week randomized clinical trial involving 24 adult men and women with *DSM-IV* bipolar depression, Chengappa et al.[13] compared inositol (12 g/day) with placebo and demonstrated that among the 22 subjects who completed the trial, six (50%) of the inositol-treated subjects showed improved depression, as indicated by a 50% or greater decrease in the baseline Hamilton Depression Rating Scale (HAM-D) score and a Clinical Global Improvement (CGI) scale score change of "much" or "very much" improved, compared to three (30%) subjects assigned to placebo. However, this study was underpowered to detect a statistically significant difference.

In a double-blind placebo-controlled study involving healthy volunteers and using magnetic resonance spectroscopy to measure the concentration of both *myo*-inositol and phosphomonoesters, Silverstone et al.[14] demonstrated that lithium therapy depletes brain stores of inositol by blocking the conversion of inositol monophosphates to *myo*-inositol, and that this effect is especially apparent after phosphoinositol cycle stimulation. Subsequently, using high-resolution nuclear magnetic resonance (NMR) spectroscopy, O'Donnell, Silverstone, et al.[15] observed a significant increase in the concentration of inositol monophosphates and a significant decrease in *myo*-inositol concentration in the brains of rats chronically treated with lithium (and/or sodium valproate) compared to saline-treated controls.

Polyuria-polydipsia syndrome is a common adverse effect associated with lithium therapy and can affect up to 60% of patients taking the medication for at least 1 year.[16,17] Preliminary research indicated that low-dose inositol could reverse polyuria-polydipsia in rats treated with lithium and that oral inositol (3 g/day) ameliorates lithium-induced polyuria-polydipsia as rated subjectively by patients.[11] Levine et al.[18] injected daily inositol or "artificial CSF i.c.v." to rats exhibiting lithium-induced polydipsia and observed that inositol i.c.v. reversed lithium-induced polydipsia, but that kidney inositol levels in lithium-treated rats were not different from controls. These findings suggest that inositol may alleviate symptoms of lithium-induced polydipsia via a central effect, but has no direct effect on lithium-induced polyuria. These researchers also conducted a double-blind crossover study involving seven patients that compared 6 g oral inositol daily versus placebo, each given for 2 weeks. Inositol did not reverse lithium-induced polyuria, as measured by 24-hour urine volume and urine specific gravity. However, subjective report of symptomatology was significantly improved in subjects taking inositol versus placebo, possibly resulting from alleviation of polydipsia.

Psoriasis is an adverse effect associated with long-term use of lithium in many patients. In a randomized, double-blind, placebo-controlled, crossover clinical trial, Allan et al.[19] compared the effects of inositol administration in 15 patients with psoriasis while undergoing lithium therapy with the effects in 11 patients with psoriasis not taking lithium. The inositol had a significantly beneficial effect on the psoriasis of patients taking lithium, in contrast to a lack of effect on psoriasis of patients not receiving lithium.

Some animal studies suggested that administration of pharmacological doses of inositol reverses behavioral effects of lithium.[20] Inositol derived from inositol phosphate breakdown appears to be recycled for use in membranous phosphatidylinositol. Belmaker et al.[21,22] proposed that inositol depletion was central to the action of lithium action and relevant to treatment of adverse effects associated with lithium therapy. Within this hypothesis, lithium's depletion of the recyclable inositol pool would affect hyperactivated systems while leaving isosystems unaffected. Berridge[23] similarly found that lithium only inhibits phosphoinositide-derived second messengers of

activated systems. These findings and those of clinical trials consistently indicate that concomitant administration of inositol during lithium therapy does not interfere with the efficacy of the treatment of individuals with bipolar disorder.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing lithium for patients with bipolar affective disorders are advised to consider concomitant inositol administration, especially when intractable psoriasis occurs and continued lithium therapy is deemed necessary. Inositol (e.g., 500 mg three times daily) could ameliorate adverse effects of lithium therapy without reducing the drug's therapeutic effectiveness; such nutrient administration may also provide therapeutic value independent of conventional pharmacological treatment.

Although the beneficial effects of inositol coadministration from clinical trials are encouraging, further research through well-designed clinical trials is warranted to investigate further the safety and efficacy of this combination and to develop clinical guidelines for therapeutic application. Pending findings from such investigations, it would be premature generally to recommend concomitant use of lithium and inositol for treatment or prevention of adverse effects.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

5-Hydroxytryptamine Receptor Agonists (Triptans)

Almotriptan (Axert), eletriptan (Relpax), frovatriptan (Frova), naratriptan (Amerge), rizatriptan (Maxalt), sumatriptan (Imitrex), zolmitriptan (Zomig).

Triptans (5-hydroxytryptamine receptor agonists) are a primary pharmacological therapy for migraines within conventional practice. Theoretically, concomitant administration of high-dose *myo*-inositol and medications in this class may produce additive effects. Evidence from qualified case reports or human trials is lacking to determine the occurrence, conditions, and clinical significance of this potential interaction.

Careful monitoring is advised for concurrent or consecutive use of high-dose *myo*-inositol with triptans. Either or both agents should be discontinued if symptoms suggestive of serotonin syndrome develop. This has not been reported, but there is little clinical experience in this area. Human trials are warranted.

Antibiotics/Antimicrobials

Antibiotics and Antimicrobials

Intestinal microflora play a critical role in biosynthesis of many B vitamins, particularly converting phytate/phytic acid from dietary sources into inositol. The adverse impact of repeated courses or high doses of broad-spectrum antibiotics on these commensal microbiota, and thus conversion of phytic acid to inositol, is probable. However, evidence is lacking to determine the frequency, character, and implications of such effects. Current knowledge suggests that the probability of a clinically significant adverse effect is low for most individuals because this inositol production pathway accounts for a minor part of inositol formation. Nevertheless, specific evidence is lacking to disprove or confirm the occurrence and clinical implications of this potential interaction. Further research is warranted. Physicians prescribing broad-spectrum antibiotics are generally advised to restore healthy intestinal ecology by administering diverse and vigorous cultures, providing 10 billion viable organisms daily of probiotic flora for a minimum of 3 weeks, although in many cases it may take 6 months of daily probiotic intake to reestablish optimal bowel flora.

Selective Serotonin Reuptake Inhibitor (SSRI) Antidepressants

Citalopram (Celexa), escitalopram (S-citalopram; Lexapro), fluoxetine (Prozac, Sarafem), fluvoxamine (Faurin, Luvox), paroxetine (Aropax, Deroxat, Paxil, Seroxat), sertraline (Zoloft).

In a randomized, controlled, double-blind augmentation trial, Nemets et al.[24] found that inositol coadministration did not improve depression in SSRI treatment failures. Comparing single-photon emission computed tomography (SPECT) on 14 subjects diagnosed with OCD before and after 12 weeks of treatment with inositol, Carey et al.[25] concluded that "inositol effects a clinical response through alternate neuronal circuitry to the SSRIs." Some research has suggested that inositol helps reverse desensitization of serotonin receptors.[26] Theoretically, high-dose *myo*-inositol might have additive effects with SSRIs and, in fact, has been recommended as an adjunctive therapy for people diagnosed with OCD who do not respond to SRIs (clomipramine and SSRIs).[27] Doses of 18 g/day have been well tolerated in conjunction with SSRIs for the treatment of OCD, although the addition of inositol did not provide any added benefit over SSRI alone.[28]

Careful monitoring is advised for concurrent or consecutive use of high-dose *myo*-inositol with SSRIs. Either or both agents should be discontinued if symptoms suggestive of serotonin syndrome develop. This has not been reported, but there is little clinical experience in this area.

Valproic Acid and Related Anticonvulsant Medications

Evidence: Divalproex semisodium, divalproex sodium (Depakote), sodium valproate (Depacon), valproate semisodium, valproic acid (Depakene, Depakene Syrup).
Extrapolated, based on similar properties: Carbamazepine (Carbatrol, Tegretol), clonazepam (Klonopin), clorazepate (Tranxene), ethosuximide (Zarontin), ethotoin (Peganone), felbamate (Felbatol), fosphenytoin (Cerebyx, Mesantoin), levetiracetam (Keppra), mephenytoin, mephobarbital (Mebaral), methsuximide (Celontin), oxcarbazepine (GP 47680, oxycarbamazepine; Trileptal), phenobarbital (phenobarbitone; Luminal, Solfoton), phenytoin (diphenylhydantoin; Dilantin, Phenytek), piracetam (Nootropyl), primidone (Mysoline), topiramate (Topamax), trimethadione (Tridione), vigabatrin (Sabril), zonisamide (Zonegran).

O'Donnell et al.[12] found that the brains of rats treated with sodium valproate exhibited a significant increase in the concentration of inositol monophosphates and a significant decrease in *myo*-inositol concentration compared with saline-treated controls. These unexpected results suggest that both lithium and sodium valproate may share a common mechanism of action in the treatment of bipolar disorder through actions on the phosphoinositol cycle.

Chengappa et al.[13] reported doses of 12 g/day inositol being well tolerated in combination with either valproic acid or carbamazepine.[13]

Clinical trials of concomitant use of valproate and *myo*-inositol in bipolar disorder would be of interest because inositol might be useful in preventing or treating the depressive cycles.

NUTRIENT-NUTRIENT INTERACTIONS

Calcium, Iron, and Zinc

Phytic acid or phytate, the form of inositol in plant food sources, has the strong ability to chelate multivalent metal ions, especially calcium, iron, and zinc. The resultant binding can produce very insoluble salts that are poorly absorbed from the gastrointestinal tract. Thus, high dietary intake of phytate can result in poor bioavailability of these minerals. However, available evidence indicates that standard oral preparations of inositol do not exert a similar effect on absorption of these nutrients.[29]

The 29 citations for this monograph, as well as additional reference literature, are located under Inositol on the CD at the back of the book.

Melatonin

Nutrient Name: Melatonin.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Benzodiazepines ≈≈/☼/⊕⊕	Benzodiazepines may suppress and/or deplete melatonin by one or more mechanisms, including suppression of the dark-induced increase of pineal N-acetyltransferase activity. Clinical significance unclear but disruption of sleep cycle dynamics could be significant. Coadministration of melatonin could be used for synergistic effect and/or to ameliorate withdrawal symptoms from benzodiazepine insomnia treatment by re-establishing a regular sleep cycle. Further research warranted based on encouraging preliminary findings.	Coadminister, especially if melatonin deficiency present. Coadminister for synergistic effect or transition, with supervision.
Beta1-Adrenoceptor Antagonists ≈≈≈/☼	With chronic use, beta blockers may suppress melatonin synthesis by blocking pineal adrenergic beta-1 receptors. Evidence of clinically significant adverse effect on sleep cycle, but may vary according to agent, patient, etc.	Coadminister to prevent or correct sleep disturbances.
Chemotherapy (and radiotherapy) ☼/⊕⊕	Coadministration of chemotherapeutic agents and high-dose melatonin can ameliorate adverse drug effects and enhance chemotherapy cytotoxicity. Diverse and preliminary consistent supportive evidence; probable clinical significance. Therapeutic methodology evolving.	Coadminister. Supervise and monitor.
Corticosteroids, oral ◇≈≈/?	Exogenous corticosteroids may suppress melatonin synthesis and reduce amplitude of the rhythmic melatonin production. Melatonin may reduce adverse effects but could theoretically suppress corticosteroid activity. Evidence of interaction is suggestive but inconclusive.	Insufficient evidence to support generalized recommendation. Monitor for interference with drug activity if used concurrently.
Fluoxetine ≈≈/✗	Fluoxetine can decrease melatonin levels. Exogenous melatonin may neutralize intended inhibitory action on tryptophan-2,3-dioxygenase by fluoxetine. Preliminary evidence suggests reasonable probability of clinically significant adverse interaction. Consider alternative antidepressant if sleep disturbed.	Avoid concomitant use.
Fluvoxamine ⊕⊕	Fluvoxamine can significantly elevate serum melatonin concentrations, most likely by inhibiting melatonin breakdown by CYP450 enzymes. Fluvoxamine levels may also rise with concomitant use. Consistent and increasingly specific evidence of clinically significant additive interaction, contributing to probable beneficial response.	Consider coadministration; may enhance effect of either or both agents. Supervise and monitor.
Haloperidol Antipsychotics ☼	Melatonin may reduce symptoms of tardive dyskinesia (TD), including such adverse effects associated with long-term use of antipsychotic medications. Preliminary supportive evidence, but likely weak clinical significance.	Consider coadministration to ameliorate adverse effects (i.e., TD). Supervise and monitor.
Interleukin-2 (IL-2) ⊕⊕/☼	Potential mutually supportive antineoplastic activity and synergistic interaction between melatonin and IL-2 in oncological care. Possible reduction of adverse drug effects. Emerging pattern of supportive evidence; probable clinical significance. Therapeutic methodology evolving.	Consider coadministration; may enhance effect of either or both agents. Supervise and monitor.
Mirtazapine ◇◇/✗/⊕	Mirtazapine can significantly increase nocturnal melatonin secretion, which may be part of its therapeutic mechanism of action. Concomitant use could be beneficial, depending on case particulars, including facilitation of reduced drug dose or use in drug withdrawal. Adverse effects possible but considered unlikely. Evidence minimal but effects plausible.	Consider coadministration; supervise closely and monitor regularly.
Nonsteroidal anti-inflammatory drugs (NSAIDs) Acetylsalicylic acid (aspirin, ASA) ☼/≈≈≈/◇≈≈	NSAIDs inhibit prostaglandin synthesis and thereby interfere with melatonin synthesis, suppress nocturnal melatonin levels, and may alter sleep patterns. Adverse effects unlikely with concomitant use. Evidence minimal but effects plausible.	Consider melatonin coadministration if sleep disruption occurs during anti-inflammatory therapy.
Tamoxifen ⊕⊕	Coadministration of tamoxifen and high-dose melatonin can ameliorate adverse drug effects and enhance chemotherapy cytotoxicity. Emerging body of supportive evidence; probable clinical significance. Therapeutic methodology evolving.	Coadminister. Supervise and monitor.

Continued

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Triptorelin ⊕⊕	Melatonin may enhance efficacy of triptorelin, and may re-establish response after patients have become refractory. Mechanism(s) of action uncertain, but may include a direct cytostatic effect, or reduction of endogenous prolactin, IGF-1 (insulin-like growth factor-1), or other tumor-dependent growth factors. Preliminary evidence supportive and beneficial effects probable where indicated.	Consider coadministration; supervise closely and monitor regularly.
Verapamil ≈≈≈	Verapamil induces increased urinary melatonin excretion through its effect on liver and kidneys.	Consider coadministration to prevent or correct sleep disturbances.

NUTRIENT DESCRIPTION

Chemistry and Form

Melatonin is an amino acid–based (indole) hormone, produced in the brain by the pineal gland. It is synthesized from the amino acid tryptophan, which is converted to the neurotransmitter serotonin, which is then converted to melatonin.

Physiology and Function

Melatonin is the central hormone involved in the regulation of numerous environmental and body cycles. As the biological timekeeper of hormone secretion, melatonin functions as a hormonal interface between the body and the environment. The greatest regulatory influence involves the daily cycle of light and darkness; melatonin production by the pineal gland begins to rise slowly with nightfall, reaching its maximum between midnight and 3 AM. After its synthesis is triggered by various external environmental cues, melatonin integrates the environmental feedback of daily and seasonal cycles, sets the biological clock, and activates bodily functions associated with these cues. The most notable example is the circadian (24-hour) cycle of sleep and waking, in which darkness triggers melatonin production, which helps to engender a feeling of sleepiness, and light suppresses secretion. Thus, melatonin possesses both phase-shifting and sleep-promoting properties. Many other cycles influence melatonin production as well, such as the annual cycle of longer and shorter days and the monthly female reproductive cycle, and many events tied to these cycles are linked to melatonin. Melatonin is metabolized by the liver after a half-life of 30 to 50 minutes.

Melatonin acts on multiple systems, appears to be high on the hierarchy of regulatory hormones (i.e., it regulates hormones that regulate hormones), and demonstrates antioxidant, antiestrogenic, and oncostatic activity. For example, melatonin appears to be such as powerful regulator of the secretion of growth hormone (GH) and gonadotropic hormones (the hormones that regulate production of sex hormones such as estrogen and progesterone) that it is a crucial element in the timing of the female reproductive cycle; rising melatonin levels may bring on menstruation, and their decline may induce a surge of luteinizing hormone (LH) and ovulation. Thus, melatonin influences menarche; the frequency, timing, and duration of menstrual cycles; and menopause. It also introduces subtle changes according to external rhythms; for example, varying melatonin levels over the course of the year result in higher estrogen in the spring and summer and higher progesterone in the fall and winter.

Human lymphocytes synthesize and release large amounts of melatonin. This melatonin appears to play a central role in the regulation of the human immune system, possibly by acting as an intracrine, autocrine, and paracrine substance. Receptors have been reported on T and B lymphocytes, and melatonin has demonstrated immune-enhancing properties in many animal studies. Physiologically, melatonin opposes the degeneration caused by elevated levels of endogenous corticosteroids (e.g., protein catabolism, suppressed immune function, and altered blood glucose metabolism). The immunosuppressive activity of exogenous corticosteroids may also be moderated by melatonin.

Various studies have shown a correlation among melatonin, aging, and life span. One proposed rationale is that the ratio of serotonin to melatonin increases as a person ages, increasing the production of various chemicals that are linked with aging. Onset of melatonin's rhythmic patterns starts at approximately 3 months of age, and young children have the highest levels of nighttime melatonin. Levels rise and then gradually start to decline during adolescence. Adults generally exhibit a 37% decline, approximately, in daily melatonin output between 20 and 70 years of age. However, controversy surrounds whether such declines are as prominent in healthy adults. These secretion patterns may contribute to sleep disruption and the tendency to shift to earlier sleep in the evening and earlier rising in the morning in the elderly population.

Numerous researchers and clinicians have suggested that the increased use of artificial light and resulting extension of the daily photoperiod of light exposure over the past century has depressed melatonin secretion and elevated the incidence of cancer in industrialized societies.[1,2]

Melatonin also functions as a powerful antioxidant, particularly in neutralizing hydroxyl, the most damaging of all oxygen-based free radicals. Administration for this purpose may be inappropriate, however, because the antioxidant effects may be offset by hormonal disruption caused by taking large doses.

Studies have also shown that melatonin decreases the internal carotid pulsability index of premenopausal women[3] and, applied topically, can reduce skin damage inflicted by ultraviolet (UV) radiation.[4] Research does not support administration as a remedy for the effects of aging; it is probably more beneficial to protect oneself from influences that inhibit melatonin.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

As a self-prescribed nutraceutical, melatonin is primarily used to induce sleep or adjust sleep cycles, especially with travel and schedule changes. Practitioners of nutritional therapeutics, particularly within the context of integrative medicine, often prescribe melatonin in the treatment of some forms of depression

and hyperactivity, at low dosages, and as part of multimodality cancer treatment protocols, using high dosages.

Historical/Ethnomedicine Precedent

None known.

Possible Uses

Age-related cognitive decline, Angelman's syndrome (sleep disturbances only), attention deficit–hyperactivity disorder (ADHD), breast cancer, cluster headaches, colon cancer, coronary heart disease, depression, epilepsy, essential hypertension, glaucoma, insomnia, jet lag, lung cancer, migraine headaches, multiple sclerosis, myoclonus, nocturnal hypertension, oxidative stress in dialysis patients (preventive), postmenopausal osteoporosis, prostate cancer, sarcoidosis, seasonal affective disorder (SAD), sudden infant death syndrome (SIDS), sleep cycle disruption, tardive dyskinesia, tinnitus.

Deficiency Symptoms

Insomnia[5] and other sleep disturbances.

Dietary Sources

Melatonin appears in foods only in trace amounts.

Nutrient Preparations Available

Time-release forms may best approximate normal physiological secretion of melatonin,[6] which typically occurs over several hours during the night. Further, a limitation of non-time-release forms is that the half-life of oral melatonin is approximately 30 to 50 minutes.

Dosage Forms Available

Capsule, tablet, sublingual tablet, time-release tablet and capsule.

Source Materials for Nutrient Preparations

Melatonin used in preparations for oral administration is derived from animals or produced synthetically.

Dosage Range

Adult

Supplemental/Maintenance: Melatonin is usually not taken on a long-term basis as a general nutritional supplement, that is, outside situational appropriateness or therapeutic strategy.
Pharmacological/Therapeutic: 0.5 to 6.0 mg nightly; up to 40 mg per day in cancer therapy.
Toxic: Melatonin is generally considered nontoxic when used in accordance with proper dosing guidelines for appropriate conditions.

Pediatric (<18 Years)

Supplemental/Maintenance: Melatonin is generally not appropriate for children, other than short-term situational use (e.g., travel, jet lag).
Pharmacological/Therapeutic: Generally not appropriate, except with managed therapeutic protocols.
Toxic: Melatonin is generally considered nontoxic for children when used in accordance with proper dosing guidelines for appropriate conditions.

Laboratory Values

Salivary melatonin concentration, urinary 6-hydroxymelatonin sulphate excretion rate, serum melatonin concentration.[7]

Note: Melatonin in a physiological setting is problematic to study, because a blood sample needs to be obtained between 3 and 4 AM without exposing the patient to light, in order to obtain a relevant measurement. Accurate interpretation of the assay requires a collection of normal levels arranged by age.

SAFETY PROFILE

Overview

Melatonin use is generally considered safe when used for appropriate conditions in accordance with standard dosage levels. Although certain predictable effects may occur, no substantive and consistent patterns of adverse effects or toxicity, based on clinical trials or qualified case reports, have been confirmed in the scientific literature. Long-term human studies on toxicity or subtle adverse effects have not been conducted. Evidence is lacking at this time of a feedback loop in which augmentation or replacement causes suppression. Nevertheless, as with administration of any exogenous hormone, regular use of melatonin over an extended period may interfere with self-regulatory mechanisms in hormonal systems.

Nutrient Adverse Effects

General Adverse Effects

Drowsiness is an expected outcome of taking melatonin, and being drowsy at inopportune times represents the most common adverse effect. Overuse or incorrect use of melatonin may disrupt circadian rhythms and sleep cycles. Morning sedation or drowsiness may indicate that the dosage used is excessive; if so, a lower dosage should reduce adverse symptoms. Somnambulism, disorientation, and vivid dreams have also been reported. Sleep disruption was observed in one small study.[8] Anxiety and irritability may occur in some individuals. Nocturnal asthma may be aggravated.[9,10]

Scattered and unqualified case reports have suggested exogenous melatonin intake as a factor in a variety of adverse phenomena, including transient psychosis, headache, abdominal cramps, decreased libido, infertility, and painful gynecomastia.[11–14] Subsequent investigation has yet to document and confirm significant patterns of adverse effects consistent with these reported individual reactions.[15–17]

Pregnancy and Nursing

Melatonin readily crosses the placenta, and its fetal effects are unknown; therefore, melatonin is not recommended during pregnancy. Given the intimate relationships between melatonin and reproductive hormones, use of melatonin by women who are pregnant is further contraindicated, pending substantive evidence of safety. The lack of research on the effects and safety of melatonin in infants warrants avoidance by mothers who are breastfeeding.

Infants and Children

An increased incidence of seizures in children with neurological disorders after melatonin administration has been reported but

not confirmed.[18] Monitoring by a qualified health care professional is warranted when use in such populations is otherwise appropriate.

Contraindications

Driving and operation of machinery should be avoided while under the influence of melatonin. Daytime use may result in fatigue and decreased alertness; other contraindications include pregnancy and nursing; fibromyalgia (if elevated melatonin),[19] insulin sensitivity or diabetes,[5] and SAD.

Some highly experimental animal trials suggest that melatonin may be contraindicated for patients with autoimmune disorders such as rheumatoid arthritis, lupus, or multiple sclerosis.

Precautions and Warnings

General

Caution is advised given the limited knowledge of hormones and their interactions and the multiple influences melatonin exerts on other regulatory hormones.

Regular use for extended periods is not advised without supervision by a health care professional experienced in nutritional therapies.

Specific Populations

Elevated melatonin levels may inhibit ovulation; prudence suggests that melatonin should generally be avoided by women attempting to conceive.

Individuals diagnosed with depression, diabetes, fibromyalgia, or schizophrenia, especially when not deficient; adolescents; individuals undergoing corticosteroid therapy for anti-inflammatory or immune suppressive effects; individuals with nocturnal asthma may experience increased inflammation with elevated melatonin levels.

Many clinicians have observed a paradoxical effect, causing alertness and insomnia, from melatonin administration in approximately 5% of patients. With those individuals, melatonin can often be successfully dosed in the morning with no adverse effects (i.e., no drowsiness).

INTERACTIONS REVIEW

Strategic Considerations

In most clinical settings, and in the vast majority of self-prescribed use by the general public, melatonin is used to treat sleep disorders (3 mg time-release form) or regulate sleep cycles (e.g., travel across multiple time zones, changing work shift). Assays for deficiency status (or excess) are available, but most experienced practitioners use sleep quality (after correcting sleep hygiene as much as possible, and ruling out sleep apnea/nocturnal myoclonic leg jerks as problems) and response to melatonin (3 mg time-release form) as the primary criteria in clinical evaluation for melatonin sufficiency.

Although consideration of its physiological role raises suspicions that many medications may interfere with melatonin secretion, human research into such effects and their clinical implications is sparse and early in its evolution. Depletion of melatonin by some pharmaceutical agents can be easily corrected with coadministration, usually at low doses, if deficiency results. In a more proactive sense, melatonin may play an important role as a component of integrative care strategies in the treatment of hormone-related cancers and sleep disturbances.

NUTRIENT-DRUG INTERACTIONS

Benzodiazepines

Alprazolam (Xanax), bromazepam (Lexotan), chlordiazepoxide (Librium), clonazepam (Klonopin, Rivotril), clorazepate (Gen-Xene, Tranxene), diazepam (Valium), estazolam (ProSom), flurazepam (Dalmane), lorazepam (Ativan), medazepam (Nobrium), midazolam (Hypnovel, Versed), oxazepam (Serax), prazepam (Centrax), quazepam (Doral), temazepam (Restoril), triazolam (Halcion).

Interaction Type and Significance

≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**

☼ **Prevention or Reduction of Drug Adverse Effect**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Benzodiazepines may deplete melatonin by suppressing the dark-induced increase of pineal *N*-acetyltransferase activity, which catalyzes the rate-limiting step in melatonin synthesis.[20] Other researchers have proposed that melatonin suppression is attributable to benzodiazepine binding sites and gamma-aminobutyric acid (GABA)–ergic transmission in the human pineal gland, suprachiasmatic nuclei, and retina.[21]

The hypnotic effect of both triazolam and melatonin can be enhanced through an additive, or possibly synergistic, effect with concomitant use. Oral melatonin may enable reversal of tolerance to benzodiazepine hypnotics that is common with long-term benzodiazepine therapy.

Research

In a double-blind clinical trial, Monteleone et al.[22] reported that serum melatonin levels in six healthy men, observed at hourly intervals during the night, after diazepam administration, were significantly lower than the corresponding values after placebo. Subsequently, in an in vivo study, Wakabayashi et al.[20] found that subcutaneous (SC) injection of diazepam 1 hour before the start of darkness significantly suppressed nocturnal elevations of pineal *N*-acetylserotonin (NAS) and melatonin contents in rats and caused a 2-hour delay in reaching the maximum melatonin level in the dark phase. McIntyre et al.[21] observed a similar suppression of plasma melatonin (and cortisol) concentrations after evening alprazolam administration in six healthy human subjects.

Ferini-Strambi et al.[23] conducted a preliminary study on the effect of coadministration of melatonin (100 mg/day) and threshold doses of triazolam (0.125 mg) on the quality of sleep in healthy volunteers. They reported significant modulation of important parameters of sleep microstructure along with improved subjective sleep quality. The authors suggested that melatonin and low benzodiazepine doses could be used together to enhance the desired effects and avoid the residual, dose-related benzodiazepine effects (e.g., morning grogginess).

Cardinali et al.[24] conducted a double-blind placebo-controlled study involving 45 subjects to investigate the efficacy of melatonin in reducing anxiolytic benzodiazepine use in elderly adults (>80 years old) with minor sleep disturbance.

They found that the combination of anxiolytic benzodiazepines in low doses and melatonin (3 mg orally, non-time-release form) produced mixed results. Melatonin advanced sleep onset by approximately 28 minutes and decreased significantly the variability of sleep onset. However, they also noted a "general lack of changes in quality of wakefulness or sleep in patients taking melatonin or placebo" and even a decrease in sleep quality during the first 2 weeks with melatonin, as compared to placebo. These researchers concluded that their findings do "not support melatonin efficacy to reduce the use of benzodiazepines in low doses [which] contrasted with the demonstrable effectiveness of melatonin to reduce benzodiazepine consumption in insomniac patients when used in hypnotic amounts."[24]

Reports

Dagan et al.[25] reported the case of a 43-year-old woman on long-term benzodiazepine therapy for chronic insomnia who demonstrated improved sleep quality, reversal of benzodiazepine tolerance, and ability to cease use of benzodiazepine medications (without a recurrence of previous withdrawal symptoms) after only 2 days of melatonin (1 mg controlled-release form at bedtime). They suggested that adjunctive melatonin could be used to ameliorate withdrawal symptoms from benzodiazepine insomnia treatment by reestablishing a regular sleep cycle.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The therapeutic action of melatonin may interact synergistically to enhance the hypnotic effect of benzodiazepines. Physicians prescribing benzodiazepines can monitor patients for melatonin deficiency and prescribe oral melatonin as appropriate. Even without confirmed melatonin deficiency, melatonin augmentation can be presented to patients as a potential tool in facilitating withdrawal from benzodiazepine therapy by moderating adverse effects and assisting them to reestablish normal sleep cycles. Thus, successful use of melatonin and triazolam together enables exploration of decreasing the dosage level of the benzodiazepine and potentially weaning the patient off the medication if sleep has improved and stabilized.

These preliminary findings are encouraging, but further research is necessary to determine whether individuals taking triazolam or another benzodiazepine might also benefit from concomitant use of melatonin (3 mg time-release preparation before bedtime) to enhance efficacy of sleep promotion and minimize adverse effects such as morning grogginess. Such research could also focus on questions of patient variability, choice and dosage of benzodiazepine agent used, pace and method of transition, and guidelines for determining appropriateness of concomitant use or benzodiazepine withdrawal. Coadministration of such agents warrants close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics, preferably within an integrative care context, to avoid excessive sedation due to additive hypnotic effects from the combined agents.

Beta-1-Adrenoceptor Antagonists (Beta-1-Adrenergic Blocking Agents)

Oral forms (systemic).
Evidence: Atenolol (Tenormin), propranolol (Betachron, Inderal LA, Innopran XL, Inderal).
Extrapolated, based on similar properties: Acebutolol (Sectral); atenolol combination drugs: atenolol and chlorthalidone (Co-Tendione, Tenoretic), atenolol and nifedipine (Beta-Adalat, Tenif), betaxolol (Kerlone), bisoprolol (Zebeta), carteolol (Cartrol), esmolol (Brevibloc), labetalol (Normodyne, Trandate), metoprolol (Lopressor, Toprol XL); combination drug: metoprolol and hydrochlorothiazide (Lopressor HCT); nadolol (Corgard), nebivolol (Nebilet), oxprenolol (Trasicor), penbutolol (Levatol), pindolol (Visken); propranolol combination drug: propranolol and bendrofluazide (Inderex); sotalol (Betapace, Betapace AF, Sorine), timolol (Blocadren).
Similar properties but evidence indicating no or reduced interaction effects: Carvedilol (Creg).
Related but evidence against extrapolation: Beta-adrenergic blocking eyedrops (Ophthalmic forms).

Effect and Mechanism of Action

Beta-adrenergic receptor antagonist agents appear to suppress melatonin synthesis with chronic use by blocking beta-1-adrenergic receptors in the pineal gland, specifically enzyme inhibition of serotonin *N*-acetyltransferase activity, along with the target beta-1 receptors in the heart.

Research

In an early animal study (1984), Steinlechner et al.[26] investigated the effect of propranolol in suppressing the normal nighttime rise in pineal melatonin levels in both Syrian hamsters and rats. Ten years later, Rommel et al.[27] examined the effect of 10 weeks' treatment with propranolol and ridazolol on melatonin synthesis and on sleep quality in 42 patients being treated for essential hypertension. Even though a 50% reduction of melatonin was observed, as measured by urinary sulfatoxymelatonin excretion rates before and after 6 and 10 weeks of beta-blocker administration, no significant adverse effects were reported in a standardized self-rating sleep inventory. These researchers suggested that pineal mechanisms were able to compensate for the drug-induced blockage of the β_1-adrenergic receptor transduction system and maintain the melatonin signal sufficiently to continue relatively normal sleep patterns. More recently, Stoschitzky et al.[28] conducted a randomized, double-blind, placebo-controlled, crossover study involving 15 healthy subjects, in which a 6-sulfatoxymelatonin (aMT6s) radioimmunoassay was performed subsequent to single oral doses of several beta blockers [(R)-propranolol, (S)-propranolol, (R)-atenolol, (S)-atenolol, (R,S)-carvedilol, (R,S)-verapamil] or placebo. They found that only the specifically beta-blocking (S)-enantiomers of propranolol and atenolol decreased the nocturnal production of melatonin and concluded that beta blockers decrease melatonin release through specific inhibition of β_1-adrenergic receptors and could thereby induce sleep disturbances.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Sleep disturbances are a well-known adverse effect of beta-adrenoreceptor blocker therapy. Physicians prescribing beta blockers are advised to query patients about changes in sleep patterns subsequent to medication. Assessment of melatonin levels for deficiency state can be confirmatory but may not be

necessary. A clinical trial of melatonin (2-3 mg/day, preferably sustained-release preparation, before bedtime) may compensate for drug-induced depletion pattern and facilitate restoration of healthy sleep patterns. No evidence exists at this time to indicate that such melatonin intake would interfere with the therapeutic action of the beta blockers.

Chemotherapy and Radiotherapy

Including: Cisplatin (*cis*-diaminedichloroplatinum, CDDP; Platinol, Platinol-AQ), cyclophosphamide (Cytoxan, Neosar), docetaxel (Taxotere), doxorubicin (Adriamycin, Rubex), etoposide (Eposin, Etophos, VePesid, VP-16), fluorouracil (5-FU; Adrucil, Efudex, Efudix, Fluoroplex), gemcitabine (Gemzar), irinotecan (camptothecin-11, CPT-11; Campto, Camptosar), methotrexate (Folex, Maxtrex, Rheumatrex), paclitaxel (Paxene, Taxol), tumor necrosis factor alpha (TNF-α).
See also Interleukin 2 (IL-2), Tamoxifen, and Triptorelin.

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**
⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
◉ **Emerging**

Effect and Mechanism of Action

Melatonin, at high dosages (typically 10-20 mg/day, often as high as 50 mg/day), has been used in combination with a variety of chemotherapeutic agents to ameliorate adverse drug effects and enhance chemotherapy cytotoxicity. At this point, published research indicates that melatonin's activity is attributable to its ability to reduce oxidative stress and inflammation, directly influence the neuroendocrine-immune system regulatory axis, promote apoptosis of cancer cells, and cause release of immunomodulating cytokines by activated T cells and monocytes.[29-34]

Research

Neri et al.[35] (1994) conducted a 12-month clinical trial in which 22 patients with metastatic renal cell carcinoma were treated with the combination of human lymphoblastoid interferon (IFN), 3 mega units (MU) intramuscularly three times per week, and melatonin, 10 mg/day orally, and then evaluated for response and toxicity. Three complete and four partial remissions (33%) were reported among the 21 evaluable patients, and nine achieved stable disease; five progressed. General toxicity was mild, with adverse effects generally of moderate severity and reversible. Several years later, these Italian researchers conducted immunoradiometric assays for tumor necrosis factor alpha (TNF-α); interleukins 1, 2, and 6 (IL-1, IL-2, IL-6); and interferon gamma (IFN-γ) after administering melatonin, 10 mg/day orally, for 3 months to 31 patients with advanced solid tumors (7 gastric, 9 enteric, 8 renal, 5 bladder, 2 prostate) who were unresponsive to chemotherapy and radiotherapy. After 3 months of therapy, marked by an absence of adverse reactions, 12 patients (39%) reported an improvement in their general well-being, demonstrated significant decrease of IL-6 circulating levels, and showed disease stabilization with no further growth of either the primary tumor or metastases.[31]

In a randomized preliminary study, Brackowski et al.[36] investigated the effects of TNF-α versus combined TNF-α and melatonin in the treatment of 14 advanced-cancer patients with metastatic solid tumors for whom no effective conventional therapy was available. Those patients receiving melatonin were administered 40 mg/day orally, starting 7 days before the TNF-α. Five consecutive days of intravenous (IV) recombinant human TNF-α was then administered at 0.75 mg/day. Although many adverse effects of TNF-α therapy were common to both groups, lymphocyte mean number observed at the end of TNF-α infusion was significantly higher and asthenia and hypotension significantly less frequent in subjects receiving both agents. The authors concluded that this small trial suggested that melatonin coadministration offered a strong possibility of modulating TNF-α toxicity and biological activity. Nevertheless, while this study utilizing TNF-α is theoretically interesting, TNF-α as a therapy is strictly in the experimental phase and not being used clinically.

Over more than a decade, Lissoni et al.[37-42] have conducted a series of clinical trials investigating potential roles for melatonin within emerging integrative approaches to cancer care, with a focus on patients in a poor clinical state. Initially, they looked at using melatonin in conjunction with radiotherapy in treating patients with brain glioblastomas, reporting that this "radioneuroendocrine strategy . . . may prolong the survival time and improve the quality of life of patients" affected by this condition known for very poor prognosis.[37] In a small, randomized, controlled study involving 50 patients with unresectable brain metastases caused by solid neoplasms were treated with steroids and anticonvulsants as supportive care alone or in combination with 20 mg melatonin each evening. Among subjects receiving only steroids and anticonvulsants, 88% (21 of 26) died within 1 year, compared with 63% (15 of 24) in the group who also received melatonin. The survival at 1 year, free-from-brain-progression period, and mean survival time were significantly higher in patients who had received the melatonin, whereas steroid-induced metabolic and infective complications were significantly more frequent in those treated only with steroids and anticonvulsants.[38] In 1997, Lissoni et al.[39] published the results of a randomized study comparing combination cisplatin and etoposide chemotherapy versus cisplatin, etoposide and melatonin, "chemoendocrine therapy" as they have termed it, as a first-line treatment of advanced non–small cell lung cancer (NSCLC) patients. Although higher in patients receiving melatonin, improvement in the tumor response rate was not statistically significant. However, compared to subjects who received chemotherapy alone, patients treated with concomitant chemotherapy and melatonin demonstrated a significantly higher percentage of 1-year survival and greater tolerance of chemotherapy, particularly a significantly lower incidence of myelosuppression, neuropathy, and cachexia. Also in 1997, Lissoni et al.[40] conducted a clinical trial of 80 individuals with a range of advanced metastatic solid tumors and found that combining 20 mg melatonin each evening with various chemotherapeutic regimens measurably reduced several common chemotherapy-induced adverse effects. Subsequently, this same team of Italian researchers reported decreased toxicity and increased efficacy of cancer chemotherapy using melatonin in a randomized trial involving 250 patients with metastatic solid tumors. Chemotherapy consisted of cisplatin plus etoposide or gemcitabine alone for lung cancer; doxorubicin alone, mitoxantrone alone, or paclitaxel alone for breast cancer; 5-FU plus folinic acid for gastrointestinal tumors; and 5-FU plus cisplatin for head and neck cancers. Compared to patients treated with antineoplastic agents alone, those treated with melatonin (20 mg/day orally) and chemotherapy concomitantly demonstrated significantly higher 1-year survival rate and objective tumor regression rate, as well as reduced frequency of thrombocytopenia,

neurotoxicity, cardiotoxicity, stomatitis, and asthenia.[41] Subsequent studies using melatonin in conjunction with conventional chemotherapy (e.g., irinotecan, etoposide, cisplatin) have carried these research findings into further development.[42,43]

More recent animal research has noted that melatonin may provide a protective effect against doxorubicin (Adriamycin) toxicity, cisplatin-induced acute renal injury, and doxorubicin-induced cardiotoxicity.[44-46]

Birdsall et al.[47] and Cancer Treatment Centers of America conducted an exploratory trial to investigate effects of concomitant naturopathic therapies on clinical tumor response to external beam radiation therapy for early-stage prostate cancer (tumor stages 1b through 2, N0,M0). External beam radiation therapy of up to 72 Gy was given to 22 patients on a conventional 8-week treatment regimen while the 13 patients in the naturopathic group received at least one antioxidant preparation, with the most frequent antioxidant naturopathic treatments including green tea extract, melatonin, and a high-potency multivitamin, vitamin C, or vitamin E. "All patients were monitored for at least 12 months (range 12-42) and no patient received concomitant hormonal therapy." The investigators reported that in the patients "who did not receive naturopathic [antioxidant] treatments, the median pretreatment PSA level was 5.4 ng/mL, the median PSA nadir was 0.66 ng/mL, and the median time to PSA nadir was 16.0 months," while in the "patients who did receive naturopathic treatments, the corresponding values were 5.8 ng/mL; 0.59 ng/mL; and 16.0 months." One tumor treatment failure occurred in the nonnaturopathic group "based on PSA elevation >2 ng from nadir which occurred at 14 months"; there were no treatment failures in the patients who received concomitant naturopathic regimens (*PSA*, prostate-specific antigen; *CAM*, complementary and alternative medicine). The authors noted as "also significant that 9/9 patients in the non-CAM group were considered to be low risk (based on pretreatment PSA levels of 4-10 ng) whereas 3 patients in the CAM group were classified as intermediate risk (PSA >10-20 ng) and 1 patient as high risk (PSA >20 ng)." Thus, the authors concluded that "concomitant naturopathic treatment does not appear to inhibit the capacity of external beam radiation therapy to control localized prostate cancer, and does not interfere with either the magnitude of the response, the velocity of the response, or its durability for at least 1 year." They added that these "results provide definitive evidence that antioxidant-based CAM modalities, designed to improve patient tolerance, quality of life, and possibly improve survival, do not inhibit tumor responses that depend on oxidative [tumor] killing mechanisms elicited by external beam radiation therapy."[47] Although encouraging, this small, retrospective study did not have sufficient power to draw any statistically significant conclusions. Similar studies involving much larger groups of patients receiving radiotherapy are warranted.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Further research with large, well-designed clinical trials is essential, but melatonin is already playing a role in many cancer treatment protocols employing multiple therapeutic modalities within an integrative clinical strategy. Many clinicians working with difficult cases have been offering this option to patients facing poor prognoses. Emerging clinical practices have begun to produce operative interventions based on collaboration of oncologists and other health care professionals experienced in both conventional pharmacology and nutritional therapeutics.

In many clinics providing integrative oncology care, melatonin has become part of therapeutic protocols used in the treatment of almost every cancer type and chemotherapy regimen, to mitigate adverse effects and enhance efficacy. Many such care facilities consider the human clinical trial data compelling enough to extrapolate using melatonin in most patients. The only patient population for whom many experienced practitioners do not routinely use melatonin is with hematological malignancies, because immune stimulation is potentially contraindicated.

The usual dosage of melatonin ranges from moderate (10 mg daily) to extremely high (>40 mg daily) and inherently requires close supervision and regular monitoring. Physicians and other health care professionals may consider reviewing the potential for such synergistic therapies with appropriate patients and provide referral information to centers specializing in such integrative approaches.

Corticosteroids, Oral

Betamethasone (Celestone), cortisone (Cortone), dexamethasone (Decadron), fludrocortisone (Florinef), hydrocortisone (Cortef), methylprednisolone (Medrol), prednisolone (Delta-Cortef, Orapred, Pediapred, Prelone), prednisone (Deltasone, Liquid Pred, Meticorten, Orasone), triamcinolone (Aristocort).

Interaction Type and Significance

◇≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**

? **Interaction Likely but Uncertain Occurrence and Unclear Implications**

Probability:
4. Plausible

Evidence Base:
☐ **Inadequate**

Effect and Mechanism of Action

Physiologically, endogenous melatonin suppresses corticosteroid activity and opposes the degeneration caused by elevated levels of endogenous corticosteroids. However, in looking at exogenous intake, administration of corticosteroids, as dexamethasone, can suppress melatonin synthesis, at least in healthy subjects.

Research

Researchers found that melatonin protects rats from injurious effects of dexamethasone in a rat model.[48] In a small, controlled trial, researchers found that administration of a single dose of dexamethasone produced measurable depression of melatonin synthesis in 9 of 11 healthy subjects.[49] Animal studies have found that prolonged treatment with dexamethasone reduces the amplitude of the rhythmic melatonin production.[50]

In potentially related research, Pawlikowski et al.[51] conducted a study on the effects of 6 months' melatonin treatment on sleep quality and serum concentrations of cortisol, as well as estradiol, dehydroepiandrosterone sulfate (DHEA-S), and somatomedin C, in elderly women. They found that melatonin treatment (2 mg each evening) did not significantly change cortisol levels.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

At this point, evidence as to the clinical significance of an apparent interaction between corticosteroids and melatonin is suggestive but inconclusive. Although short-term administration of a corticosteroid agent in an experimental setting may transiently reduce melatonin levels in healthy volunteers, little is known or can be extrapolated from such findings as to

the potential effect of long-term corticosteroid therapy on melatonin levels and function in individuals experiencing various dysfunctional or pathological states. Sleep disturbances are a common adverse effect of steroid medications. Coadministration of exogenous melatonin may counter adverse effects of corticosteroids, including melatonin depletion. Exogenous melatonin could theoretically interfere with the action of corticosteroid medications; however, since corticosteroids are often prescribed for symptom control, such interference would be clinically obvious in those situations. Large, well-designed clinical trials are necessary to determine the character and implications of the interaction(s) between exogenous sources of these two key hormones.

Fluoxetine

Fluoxetine (Prozac, Sarafem).
Similar properties but evidence lacking for extrapolation: Citalopram (Celexa), duloxetine (Cymbalta), escitalopram (S-citalopram; Lexapro), fluvoxamine (Faurin, Luvox), paroxetine (Aropax, Deroxat, Paxil, Seroxat), sertraline (Zoloft), venlafaxine (Effexor).

Interaction Type and Significance

≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, with Professional Management**

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Fluoxetine can decrease melatonin levels in humans by a mechanism that is as yet not fully understood. Selective serotonin reuptake inhibitors (SSRIs) inhibit, with varying degrees of inhibition potency, production of serotonin (5-HT) from 5-methoxytryptamine (5-MT), a metabolite and precursor of melatonin, normally catalyzed by polymorphic cytochrome P450 2D6 (CYP2D6). Based on findings of a study on the effect of administering 5-MT *O*-demethylase from liver microsomes extracted from CYP2D6-transgenic mice on serum 5-HT levels, Yu et al.[52] concluded that the "regeneration of 5-HT from 5-MT provides the missing link in the serotonin-melatonin cycle." They noted that up to 10% of the population lacks 5-MT *O*-demethylase and proposed that "this common inborn error in 5-MT *O*-demethylation to serotonin influences a range of neurophysiologic and pathophysiologic events."

In potentially related research, an animal model indicates that exogenous melatonin may interfere with tryptophan-2,3-dioxygenase activity, through chemical antagonism at the surface of the enzyme, and neutralize the intended inhibitory action on the enzyme by desipramine and fluoxetine. The therapeutic mechanism of desipramine and other tricyclics is unclear. However, the fundamental therapeutic mechanism of SSRIs is by definition blocking reuptake of 5-HT into the presynaptic nerve terminals after it has been secreted, thus prolonging and increasing the serotonergic tone. Tryptophan-2,3-dioxygenase is an enzyme expressed in both liver and brain tissue that is primarily responsible for catabolizing tryptophan. Its activity is not directly involved in the blocking of 5-HT reuptake in the brain. Thus, the implications of this finding for fluoxetine activity and melatonin levels remain unclear and inconclusive.

Research

In a 6-week case-control study with 20 age- and gender-matched subjects, half of whom had been diagnosed with seasonal affective disorder (SAD) and the other half healthy controls, Childs et al.[53] measured significant reductions in melatonin concentrations for both groups on administration of fluoxetine (20 mg/day). The authors noted the contrast with tricyclics and fluvoxamine, both of which increase melatonin. In an experimental rat study, Walsh and Daya[54] found that administration of exogenous melatonin counteracted the inhibitory effects of both desipramine and fluoxetine on hepatic tryptophan-2,3-dioxygenase activity and restored normal levels of enzyme activity in rats when administered in combination with either drug. The implications of this finding for the observed effect of fluoxetine decreasing melatonin levels are not clear or conclusive.

In related research, investigators found that changes in urinary excretion of 6-sulfatoxymelatonin, the principal metabolite of melatonin, distinguished antidepressant responders from nonresponders, with a significant increase observed in the former group and a significant decrease in the latter. The important role of enhanced noradrenergic function in determining clinical response to antidepressant pharmacotherapy was suggested by the high degree of correlation between clinical response and the change in 6-sulfatoxymelatonin excretion.[55]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

At this time, no definitive evidence exists to confirm whether melatonin coadministration may be appropriate or contraindicated in individuals taking fluoxetine. A generalizable answer may be elusive in light of individual variations in melatonin status and pharmacogenomic variability in response to the antidepressant.

Well-designed human trials are warranted to determine if exogenous melatonin counteracts the effects of fluoxetine in humans and whether long-term fluoxetine use induces a clinically significant melatonin depletion pattern, particularly as manifested in new or aggravated sleep disturbances. If the former condition is confirmed, melatonin would be contraindicated in patients undergoing fluoxetine therapy. If the latter, physicians observing adverse effects on sleep might consider prescribing a different antidepressant, such as one that enhances melatonin levels or allows for adjuvant use when indicated. In the absence of high-quality clinical trials, at this time it would seem reasonable to undertake careful therapeutic trials of melatonin coadministration in patients on SSRI therapy who exhibit sleep disturbances. With good patient-practitioner communication, it should be clear if the previously obtained therapeutic effects of SSRI therapy are attenuated by concomitant melatonin, in which case it should be discontinued.

Fluvoxamine

Fluvoxamine (Faurin, Luvox).
Similar properties but evidence lacking for extrapolation: Citalopram (Celexa), duloxetine (Cymbalta), escitalopram (S-citalopram; Lexapro), fluoxetine (Prozac, Sarafem), fluvoxamine (Faurin, Luvox), paroxetine (Aropax, Deroxat, Paxil, Seroxat), sertraline (Zoloft), venlafaxine (Effexor).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Fluvoxamine can significantly elevate serum melatonin concentrations. More than other SSRI agents, fluvoxamine is a potent inhibitor of several cytochrome P450 (CYP) enzymes, particularly CYP1A2, a high-affinity enzyme that is almost exclusively responsible for the metabolism of melatonin to 6-hydroxymelatonin and *N*-acetylserotonin.[56-58] Thus, fluvoxamine appears to be a specific inhibitor of melatonin degradation, that is, 6-hydroxymelatonin formation via 6-hydroxylation, thereby enhancing bioavailability of oral melatonin. This effect on the pharmacokinetics of melatonin is further subject to significant individual variability in the activity of 5-MT *O*-demethylase, the key enzyme in the conversion of 5-methoxytryptamine (5-MT), a metabolite and precursor of melatonin, to serotonin (5-hydroxytryptamine, 5-HT), and the relative inhibition potency of fluoxetine on CYP2D6; 5-MT is a specific and high-turnover endogenous substrate of CYP2D6.[52]

Research

Numerous researchers and clinicians have reported that fluvoxamine increased melatonin levels, but the mechanism, degree, and significance of this effect are only gradually becoming apparent. In a clinical trial involving healthy subjects, von Bahr et al.[56] confirmed that fluvoxamine increases serum melatonin and determined that CYP1A2 and CYP2C19 hydroxylate melatonin. Grozinger, Hartter, et al.[59] (2000) assessed serum concentrations of melatonin and fluvoxamine in five healthy male volunteers (one whom was a CYP2D6-poor metabolizer) after administration of 5 mg melatonin either with or without coadministration of 50 mg fluvoxamine, 0 to 28 hours later. The combination of the two agents produced a 17-fold higher average area under concentration-time curve (AUC) and a 12-fold higher average serum peak concentration (C_{max}) of melatonin. Further, in the CYP2D6-poor metabolizer, the AUC and C_{max} of fluvoxamine were approximately three times higher and the half-life about two times higher, with a generally more pronounced and longer-lasting effect of fluvoxamine on the pharmacokinetics of melatonin. The authors concluded that this enhanced bioavailability of oral melatonin by coadministration of fluvoxamine was caused by inhibition of melatonin elimination, rather than increased melatonin production.[59] Subsequently, using human liver microsomes and recombinant human CYP isoenzymes in vitro, this research team found that melatonin is almost exclusively metabolized by CYP1A2 to 6-hydroxymelatonin and *N*-acetylserotonin, with a minimal contribution of CYP2C19, and that fluvoxamine potently inhibited both reactions.[57]

In related research, investigators found that changes in urinary excretion of 6-sulfatoxymelatonin, the principal metabolite of melatonin, distinguished antidepressant responders from nonresponders, with a significant increase observed in the former group and a significant decrease in the latter. The important role of enhanced noradrenergic function in determining clinical response to antidepressant pharmacotherapy was suggested by the high degree of correlation between clinical response and the change in 6-sulfatoxymelatonin excretion.[55]

Further more, SSRIs inhibit, with varying degrees of inhibition potency, production of serotonin (5-HT) from 5-MT, a metabolite and precursor of melatonin, normally catalyzed by polymorphic cytochrome P450 2D6 (CYP2D6). Based on findings of a study looking at the effect of administering 5-MT *O*-demethylase from liver microsomes extracted from CYP2D6-transgenic mice on serum 5-HT levels, Yu et al.[52] concluded that the "regeneration of 5-HT from 5-MT provides the missing link in the serotonin-melatonin cycle." They noted that up to 10% of the population lacks 5-MT *O*-demethylase and proposed that "this common inborn error in 5-MT *O*-demethylation to serotonin influences a range of neurophysiologic and pathophysiologic events."

Reports

The German team previously mentioned reported on a case where an individual with a low-amplitude melatonin profile demonstrated strongly inhibited melatonin metabolism in response to fluvoxamine therapy.[59]

Clinical Implications and Adaptations

The cumulative evidence consistently indicates that coadministration of fluvoxamine and melatonin results in significantly elevated levels of melatonin, and potentially of fluvoxamine, and provides a reasonable mechanism of action for such effects. Nevertheless, further clinical trials will be necessary to determine more fully the clinical significance of this interaction and the opportunities it might provide for an integrative therapeutic strategy, particularly in the treatment of pharmacogenomically appropriate individuals. Fluvoxamine might be used as an enhancer of melatonin, thereby offering new therapeutic possibilities of fluvoxamine. Likewise, in some situations, coadministration might enhance clinical response to fluvoxamine in otherwise–less responsive individuals. Such experimental combination therapy would warrant close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics.

Haloperidol and Related Antipsychotic Medications

Evidence: Haloperidol (Haldol).
Extrapolated, based on similar properties: Aripiprazole (Abilify, Abilitat), chlorpromazine (Largactil, Thorazine), clozapine (Clozaril), fluphenazine (Permitil, Prolixin, Prolixin Decanoate, Prolixin Enanthate), olanzapine (Symbyax, Zyprexa), prochlorperazine (Compazine, Stemetil), quetiapine (Seroquel), risperidone (Risperdal), ziprasidone (Geodon).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability:	Evidence Base:
3. Possible	○ **Preliminary**

Effect and Mechanism of Action

Tardive dyskinesia (TD) is an adverse effect of long-term antipsychotic medications that occurs in up to 50% of patients hospitalized with chronic schizophrenia. The pathophysiology of TD is incompletely understood, but both dopamine receptor supersensitivity and oxidative stress–induced neurotoxicity in the nigrostriatal system have been implicated. The rationale for investigating melatonin is based on its activity as a potent antioxidant and its ability to attenuate dopaminergic activity in the striatum and dopamine release from the hypothalamus.

Research

In a double-blind, placebo-controlled, crossover study involving 22 patients with schizophrenia, Shamir et al.[60] found that subjects receiving melatonin (10 mg daily for 6 weeks) demonstrated less severe TD symptoms after they were treated with melatonin than after they received the inactive therapy. In an editorial accompanying the Shamir paper, Glazer et al.

speculated that melatonin might be suppressing TD symptoms instead of treating them, based on its proposed mechanism of action. Furthermore, they deemed the 30% or more reduction in symptom severity as "relatively weak" and thus not attaining a 50% standard of efficacy. These editorialists concluded: "From our perspective, the treatment value of melatonin for TD is questionable."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Coadministration of antipsychotic medications and melatonin may provide a valuable tool in increasing medication compliance among individuals diagnosed with schizophrenia, as many as 40% of whom stop taking their medications because of adverse effects. This first study to demonstrate clinically meaningful improvement of TD symptoms with melatonin offers encouragement for countering at least one of the more serious adverse effects of antipsychotic medications. However, although significant, the outcome may not represent a clinically adequate intervention for the treatment and prevention of TD. Larger clinical trials are warranted. Nevertheless, because evidence is lacking for any effective alternatives, physicians prescribing haloperidol and other antipsychotic medications have the option of discussing adjunctive use of melatonin with their patients undergoing pharmacological treatment for schizophrenia.

Interleukin-2 (IL-2)

Interleukin-2 (Aldesleukin, IL-2, interleukin-2, recombinant interleukin 2, rIL-2; Proleukin).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Melatonin directly influences the neuroendocrine-immune system regulatory axis, promotes release of cytokines by activated T cells and monocytes, and demonstrates significant antioxidant activity. Whereas some research indicates that melatonin may exert significant independent antineoplastic activity, its primary use in cancer therapy protocols has been in conjunction with conventional chemotherapy, particularly interleukin 2 (IL-2). Melatonin appears to potentiate and increase the efficacy of IL-2.

Research

The Italian research team of Lissoni, Barni, et al.[61-69] conducted a series of clinical trials over the past decade investigating the efficacy of melatonin in conjunction with or after low-dose IL-2 chemotherapy. In an early preliminary study involving 14 patients with advanced solid neoplasms, they found that the combination of IL-2 and oral melatonin rendered previously resistant tumors more responsive to IL-2 therapy by enhancing IL-2 antitumor immune effect and by increasing the susceptibility of cancer cells to the cytolysis mediated by IL-2-induced cytotoxic lymphocytes.[61] That same year (1994) they published an important paper in the *British Journal of Cancer* reporting the results of a larger, randomized clinical trial involving 80 patients with a range of locally advanced or metastatic solid tumors, other than renal cell cancer and melanoma. These patients, all of whom had refused conventional chemotherapy or who had not responded to previous chemotherapy, received either low-dose IL-2 alone (3 million IU/day subcutaneously, 6 days a week for 4 weeks) or in combination with melatonin (40 mg/day orally at 8:00 PM, starting 1 week before IL-2). Whereas 3 of 41 patients treated with low-dose IL-2 plus melatonin demonstrated a complete response, none responded among those receiving IL-2 alone. Eight of 41 patients treated with both low-dose IL-2 and melatonin achieved a partial response, versus only one in the IL-2-only group. Tumor objective regression rate and mean increase in lymphocyte and eosinophil number were all significantly higher in the low-dose IL-2 plus melatonin group than in patients treated with only IL-2. Survival rate after 1 year was 19 of 41 in the group receiving both agents, versus only 6 of 30 in the IL-2 group.[61]

In subsequent years, this research team has further expanded its investigation into synergistic therapies with low-dose IL-2 and melatonin. Several studies have focused on decreased adverse effects, particularly immunosuppressive events, in addition to enhanced efficacy, from combined low-dose IL-2 and melatonin therapy, compared with various forms of interleukin therapy.[62-66] In 2000, Lissoni et al.[67] reported preliminary results suggesting that concomitant administration of SC low-dose IL-2 along with oral melatonin appeared to prolong the survival time in individuals with advanced hematological malignancies that had not responded to previous standard therapies, with results comparable to those previously reported using a more toxic immunotherapy, consisting of high-dose IL-2 alone. In exploring their long-term emphasis on psychoneuroimmunomodulation, these researchers conducted a study on the use of melatonin to abrogate the negative influence of opioids, particularly morphine-induced immunosuppression, on IL-2 immunotherapy in the treatment of renal cell cancer. Thirty patients with metastatic renal cell cancer undergoing subcutaneous IL-2 therapy were randomized to receive morphine alone or morphine plus melatonin (20 mg orally each evening). No diminished analgesic efficacy of morphine occurred among patients receiving the adjuvant melatonin, but percentage of partial responses achieved and 3-year survival percentage in patients in this group were significantly higher than among those receiving morphine alone.[68] In a related preliminary study, Lissoni et al.[69] observed that adding naltrexone (100 mg orally each morning), an opioid antagonist, significantly amplified the lymphocytosis obtained by the IL-2 and melatonin combination. Because the lymphocytosis represents the most important favorable prognostic variable predicting the anticancer efficacy of IL-2 immunotherapy, these authors proposed that further research into this novel synergistic approach to cancer neuroimmunotherapy, using IL-2 with both melatonin and naltrexone to activate T-helper type 1 (Th1) lymphocytes and suppress Th2 lymphocytes, respectively.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Further research with large, well-designed clinical trials is essential, but melatonin is already playing a role in many cancer treatment protocols employing interleukin along with other therapeutic modalities within an integrative clinical strategy. Many clinicians working with difficult cases have been offering this option to patients facing poor prognoses. Emerging clinical practices have begun to produce operative interventions based on collaboration of oncologists and other health care professionals experienced in both conventional pharmacology and nutritional therapeutics. The usual dosage of melatonin ranges from moderate (10 mg daily) to extremely high (>40 mg daily),

with 20 mg daily most common, and inherently requires close supervision and regular monitoring. It is also essential to note that the studies cited were primarily using low-dose IL-2, such as 3 million IU/day, in contrast to the standard dosing of IL-2, 30 to 60 million IU, which can be an extremely toxic regimen. Furthermore, many patients being treated with IL-2, at any dosage levels, will have to be managed in the intensive care unit (ICU) while receiving IL-2 and often can experience difficulty completing the optimal number of cycles. Consequently, the use of IL-2 in integrative oncology settings is quite limited. Physicians and other health care professionals may consider reviewing the potential for such synergistic therapies with appropriate patients and provide referral information to centers specializing in such integrative approaches.

Mirtazapine

Mirtazapine (Remeron).

Interaction Type and Significance

◈◈ **Drug-Induced Effect on Nutrient Function, Supplementation Contraindicated, Professional Management Appropriate**

✗ **Potential or Theoretical Adverse Interaction of Uncertain Severity**

⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

Probability: **4. Plausible**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Mirtazapine, an alpha-2-adrenoceptor antagonist form of nonselective serotonin reuptake inhibitor (NSRI), can significantly increase nocturnal melatonin secretion. This apparent existence of an α_2-adrenergic influence on melatonin secretion may play a significant role in the therapeutic action of mirtazapine.

Research

In a single, small study with 10 healthy volunteers, administration of mirtazapine significantly increased nocturnal melatonin secretion.[70]

Clinical Implications and Adaptations

Controlled research with a large, well-designed clinical trial is necessary to determine whether combining melatonin and mirtazapine might produce beneficial or adverse effects, particularly on the therapeutic action of mirtazapine in the treatment of individual with depression. Combined use could potentially enable mirtazapine to provide therapeutic effect at lower doses, if that activity is in part caused by elevated melatonin levels. Melatonin might also play a role in easing withdrawal symptoms and reestablishing a regular sleep cycle in individuals developing sleep disturbances during cessation of mirtazapine use. Evidence is lacking to suggest that combined use of melatonin and mirtazapine posing any significant risk. However, pending well-designed clinical trials, such coadministration warrants close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics, preferably within an integrative care context.

Nonsteroidal Anti-Inflammatory Drugs (NSAIDs) and Acetylsalicylic Acid (Aspirin)

COX-1 inhibitors (NSAIDs): Diclofenac (Cataflam, Voltaren); combination drug: diclofenac and misoprostol (Arthrotec); diflunisal (Dolobid), etodolac (Lodine), fenoprofen (Dalfon), furbiprofen (Ansaid), ibuprofen (Advil, Excedrin IB, Motrin, Motrin IB, Nuprin, Pedia Care Fever Drops, Provel, Rufen); combination drug: hydrocodone and ibuprofen (Reprexain, Vicoprofen); indomethacin (indometacin; Indocin, Indocin-SR), ketoprofen (Orudis, Oruvail), ketorolac (Acular ophthalmic, Toradol), meclofenamate (Meclomen), mefenamic acid (Ponstel), meloxicam (Mobic), nabumetone (Relafen), naproxen (Aleve, Anaprox, Naprosyn), oxaprozin (Daypro), piroxicam (Feldene), salsalate (salicylic acid; Amigesic, Disalcid, Marthritic, Mono Gesic, Saltlex, Salsitab), sulindac (Clinoril), tolmetin (Tolectin).

COX-2 inhibitor (NSAID): Celecoxib (Celebrex).

Acetylsalicylic acid (acetosal, acetyl salicylic acid, ASA, salicylsalicylic acid; Arthritis Foundation Pain Reliever, Ascriptin, Aspergum, Asprimox, Bayer Aspirin, Bayer Buffered Aspirin, Bayer Low Adult Strength, Bufferin, Buffex, Cama Arthritis Pain Reliever, Easprin, Ecotrin, Ecotrin Low Adult Strength, Empirin, Extra Strength Adprin-B, Extra Strength Bayer Enteric 500 Aspirin, Extra Strength Bayer Plus, Halfprin 81, Heartline, Regular Strength Bayer Enteric 500 Aspirin, St. Joseph Adult Chewable Aspirin, ZORprin); combination drugs: ASA and caffeine (Anacin); ASA, caffeine, and propoxyphene (Darvon Compound); ASA and carisoprodol (Soma Compound); ASA, codeine, and carisoprodol (Soma Compound with Codeine); ASA and codeine (Empirin with Codeine); ASA, codeine, butalbital, and caffeine (Fiorinal); ASA and extended-release dipyridamole (Aggrenox, Asasantin).

See also Indomethacin.

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

≈≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, Not Requiring Professional Management**

◈≈≈ **Drug-Induced Adverse Effect on Nutrient Function, Coadministration Therapeutic, with Professional Management**

Probability: **4. Plausible**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Inhibition of prostaglandin synthesis is an intended effect of nonsteroidal anti-inflammatory drugs (NSAIDs). Prostaglandins are involved in melatonin synthesis and sleep, as well as thermoregulation, in such a way that NSAID administration may inhibit melatonin synthesis. This activity provides a mechanism by which NSAIDs may alter sleep patterns.

Research

Murphy et al.[71] conducted a series of experiments in which they assessed the melatonin synthesis and body temperature (BT) in 75 subjects after administration of NSAIDs (aspirin and ibuprofen) or placebo at night in a within-subjects design. They found that normal nocturnal melatonin was suppressed, and BT decrease was attenuated, after NSAID administration versus after placebo. Lower melatonin levels were associated with a relative flattening of BT. The authors interpreted these findings as indicating that NSAID-induced prostaglandin synthesis inhibition and suppression of melatonin synthesis might explain some of the behavioral changes associated with NSAIDs, including changes in sleep.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing NSAIDs are advised to ask patients to be watchful for adverse effects on sleep and to consider melatonin (3 mg 45 minutes before bedtime) in such situations. Individuals taking melatonin for sleep disturbances may need to increase their nightly dosage to compensate for suppression by NSAIDs or consider other options for treatment of inflammation-related symptoms.

Tamoxifen

Tamoxifen (Nolvadex).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ○ **Emerging**

Effect and Mechanism of Action

Melatonin coadministration may enhance clinical efficacy and reduce adverse effects of tamoxifen antiestrogen therapy. Melatonin may directly modulate estrogen receptor (ER) expression and inhibit breast cancer cell growth. At this point, published research indicates that melatonin's activity is attributable to its ability to reduce oxidative stress and inflammation, directly influence the neuroendocrine-immune system regulatory axis, promote apoptosis of cancer cells, and cause release of immunomodulating cytokines by activated T cells and monocytes.[29-34]

Research

Animal research has shown that melatonin can inhibit human breast cancer cell growth in vitro. Using the ER-positive human breast tumor cell line MCF-7 and other cell lines, Blask et al.[72] found that glutathione is required for melatonin's oncostatic action, and that coadministration offers the potential of enhancing synergistic therapeutic effects.

Several small human trials have found that the addition of melatonin to conventional tamoxifen therapy enhanced clinical outcomes and reduced adverse effects in the treatment of breast cancer. In a pilot phase II study, Lissoni et al.[73] investigated the effects of concomitant melatonin therapy in 14 women with metastatic breast cancer who had not responded to therapy with tamoxifen alone or progressed after initial stable disease. Melatonin was given orally at 20 mg each evening, every day starting 7 days before tamoxifen, which was given orally at 20 mg daily at noon. A partial response was achieved in four patients (28.5%), after a median duration of 8 months. The treatment was well tolerated in all cases, with no melatonin-induced enhancement of tamoxifen toxicity. Combined treatment was generally associated with decreased mean serum levels of insulin-like growth factor 1 (IGF-1). In a related study, Lissoni et al.[74] tested a similar tamoxifen-melatonin protocol in 25 patients with metastatic solid tumors, other than breast cancer and prostate cancer, for whom no other effective standard therapy was available. Three patients had a partial response, and a stable disease was achieved in 13 other patients, whereas the remaining nine patients progressed. Further, survival longer than 1 year was observed in seven patients (28%). Subsequent in vitro and animal research into the use of melatonin to enhance the clinical efficacy of tamoxifen, although potentially moderating adverse effects, has produced encouraging results.[75-78]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Concomitant administration of melatonin may induce objective tumor regressions in metastatic breast cancer patients refractory to tamoxifen alone. Further research with large, well-designed clinical trials is essential, but melatonin is already playing a role in many cancer treatment protocols employing tamoxifen along with other therapeutic modalities within an integrative clinical strategy. Many clinicians working with difficult cases have been offering this option to patients facing poor prognoses. Emerging clinical practices have begun to produce operative interventions based on collaboration of oncologists and other health care professionals experienced in both conventional pharmacology and nutritional therapeutics. The usual dosage of melatonin ranges from moderate (10 mg daily) to extremely high (>40 mg daily) and inherently requires close supervision and regular monitoring, preferably within the context of multidisciplinary care. Physicians and other health care professionals may consider reviewing the potential for such synergistic therapies with appropriate patients and provide referral information to centers specializing in such integrative approaches.

Triptorelin

Triptorelin (De-capeptyl Trelstar, Trelstar LA).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Triptorelin is a luteinizing hormone–releasing hormone (LHRH) analog that causes the testes/ovaries to shut down (after an initial increase in function) and is useful for treatment of hormone-sensitive cancers in men and premenopausal women. Concomitant use of melatonin appears to enhance clinical efficacy of triptorelin, although the mechanism of action is unknown. Melatonin may stimulate hormone receptor expression on both normal and cancer cells. Melatonin has apparently inhibited the growth of some cancer cell lines, including prostate cancer, either by exerting a direct cytostatic action or by decreasing the endogenous production of some tumor growth factors, such as prolactin and IGF-1.

Research

Fourteen consecutive metastatic prostate cancer patients with poor clinical conditions, refractory or resistant to a previous therapy with triptorelin alone, were given melatonin (20 mg orally each evening) with triptorelin intramuscular injections starting after 7 days and then repeated every 28 days. Eight of the patients (57%) demonstrated a decrease in PSA serum levels greater than 50%, and PSA mean concentrations significantly decreased in those receiving the combined triptorelin and melatonin therapy; mean serum levels of both prolactin and IGF-1, important tumor growth factors, also decreased significantly. Three of five patients with persistent thrombocytopenia before the study experienced a normalization of platelet number. Importantly, 9 of 14 patients (64%), who had been evaluated as being in poor clinical condition, achieved survival longer than 1 year.[79]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The findings from preliminary research suggests that the concomitant administration of melatonin may facilitate reversal of clinical resistance to triptorelin, and possibly other LHRH

analogs, and improve drug response, outcomes, and quality of life in patients with metastatic prostatic cancer. Larger, well-designed clinical trials appear warranted.

Verapamil

Verapamil (Calan, Calan SR, Covera-HS, Isoptin, Isoptin SR, Verelan, Verelan PM).
Extrapolated, based on similar properties: Verapamil combination drug: trandolapril and verapamil (Tarka).

Interaction Type and Significance

≈≈≈ **Drug-Induced Nutrient Depletion, Supplementation Therapeutic, Not Requiring Professional Management**

Probability:
2. Probable

Evidence Base:
○ Preliminary

Effect and Mechanism of Action

Verapamil influences the renal and hepatic handling of melatonin, resulting in increased urinary melatonin excretion.

Research

After noting that individuals with primary hyperparathyroidism have higher serum melatonin concentrations during active disease than after surgical cure, Wikner et al.[80] conducted a three-part experiment to determine whether exogenous hypercalcemia, as induced by calcium channel blockers such as verapamil, would similarly inhibit nocturnal melatonin secretion. After eight healthy volunteers were treated, on separate occasions, with oral verapamil and placebo, verapamil increased urinary melatonin excretion significantly (by 67%), but did not alter excretion of 6-sulphatoxymelatonin, the primary melatonin metabolite excreted by the kidneys. Verapamil did not affect nocturnal melatonin secretion.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Although the mechanism of this proposed depletion pattern appears consistent with known research and pharmacological principles, its clinical significance remains undetermined at this time. Larger, well-designed clinical trials are warranted, preferably involving subjects with medical conditions for which verapamil would normally be prescribed. Pending such evidence, physicians prescribing verapamil or other calcium channel blockers may want to query relevant patients regarding sleep disruption as a potential adverse effect and discuss the option of corrective melatonin intake, usually 2 to 3 mg daily, before bedtime. Although evidence is lacking to indicate a significant risk from melatonin administration, close supervision and regular monitoring may be warranted in the event that the option to supplement is chosen, preferably within an integrative care context.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Anticoagulants

Anticoagulants

Melatonin may theoretically increase the risk of bleeding from anticoagulant medications such as warfarin. However, well-founded case reports and substantive evidence from well-designed clinical trials is lacking.

Bupropion, Desipramine, Tranylcypromine

Bupropion (Wellbutrin), desipramine (Norpramin, Pertofrane), tranylcypromine (Parnate).

The research by Walsh and Daya[54] previously discussed regarding fluoxetine and melatonin's interference with tryptophan-2,3-dioxygenase activity could theoretically be extrapolated to related antidepressant medications. However, well-founded case reports and substantive evidence from well-designed clinical trials are lacking. Pending clarification, concurrent melatonin should be avoided outside the context of close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics, preferably within an integrative care context.

Clonidine; Methoxamine

Clonidine (Apo-Clonidine, Catapres Oral, Catapres-TTS Transdermal Dixarit, Duraclon, Novo-Clonidine, Nu-Clonidine); combination drug: clonidine and chlorthalidone (Combipres).
Methoxamine (Vasoxyl).

In an ex vivo experiment using thoracic aorta excised from male rats, melatonin reduced the efficacy, but not potency, of the contractile responses to methoxamine and clonidine by relaxing vascular smooth muscle. Low doses of melatonin appear to impair alpha-1- and alpha-2-adrenergic responses without changes in the beta-adrenergic response of vascular smooth muscle. The experimental data suggest that the inositol phosphate pathway may be involved in this relaxation, but the mechanism remains undetermined.[81]

Well-founded case reports and substantive evidence from well-designed clinical trials are lacking to suggest whether exogenous melatonin might substantively interfere with the effects of methoxamine and clonidine in humans. Pending clarification, concurrent melatonin should be avoided outside the context of close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics, preferably within an integrative care context.

Cyclosporine

Cyclosporine (Ciclosporin, cyclosporin A, CsA; Neoral, Sandimmune, SangCya).
Animal research using rats indicates that concomitant administration of melatonin during cyclosporin A therapy may reduce nephrotoxic effects of the drug, possibly by reducing oxidative stress.[82] Further research, moving toward clinical trials, appears warranted by the findings from this preliminary study.

Cytochrome 1A2 Isoenzyme Substrates

Caffeine, clozapine (Clozaril), haloperidol (Haldol), tacrine (tetrahydroaminoacridine, THA; Cognex), theophylline/aminophylline (Phyllocontin, Slo-Bid, Slo-Phyllin, Theo-24, Theo-Bid, Theocron, Theo-Dur, Theolair, Truphylline, Uni-Dur, Uniphyl); combination drug: ephedrine, guaifenesin, and theophylline (Primatene Dual Action); other medications.

Research involving SSRIs (see previous section) suggests a high probability that melatonin, both at physiological levels and after oral administration, might result in interaction with drugs metabolized by CYP1A2.[20,56,58]

Cytochrome 2C9 Isoenzyme Substrates

NSAIDs, phenytoin (diphenylhydantoin; Dilantin, Phenytek), warfarin (Coumadin, Marevan, Warfilone), zafirlukast (Accolate, Accoleit, Vanticon), other medications.

In vitro data suggest melatonin may affect the disposition of drugs metabolized by the CYP2C9 isoenzyme system.[58]

Estrogens, Progestins, and Estrogen-Progestin Combinations

Hormone replacement therapy (HRT): Estrogen-containing and synthetic estrogen and progesterone analog medications. Oral contraceptives (OCs): Monophasic, biphasic, and triphasic estrogen preparations (synthetic estrogen and progesterone analogs).

Melatonin demonstrates antiestrogenic activity. More fundamentally, given current knowledge of the interplay between melatonin and female hormones, an interaction will likely be revealed with concerted investigation and well-designed clinical trials. The incidence of adverse and unintended effects from administration of exogenous hormones suggest the potential for some of those effects to be attributable, at least in part, to their influence on melatonin and the manner in which the physiological self-regulatory mechanisms of the endocrine system express themselves in daily, monthly, and annual cycles.

Indomethacin

Indomethacin (Indomethacin; Indocin, Indocin-SR).

In a rat model, Singh et al.[83] found that by scavenging of oxygen-derived free radicals, a combination of melatonin (20 mg/kg) and beta-carotene decreased the ulcer index and lipid peroxidation, and reduced the decrease in antioxidant enzyme levels, in exerting a protective effect against indomethacin-induced gastric injury.

Vitamin B_6–Depleting Drugs

Estrogen, hydralazine, 1-hydrazinophthalazine monohydrochloride; Apresoline; combination drugs: hydralazine and hydrochlorothiazide (Apresazide); hydralazine and isosorbide dinitrate (BiDil); loop diuretics, OCs, penicillamine (D-penicillamine; Cuprimine, Depen), theophylline; other drugs.

Drugs that deplete vitamin B_6 may induce a deficiency of pyridoxine that affects the tryptophan-serotonin-melatonin pathway and inhibits the synthesis of melatonin.[84-88] Pending large, well-designed clinical trials, physicians prescribing such medications may want to query relevant patients regarding sleep disruption as a potential adverse effect and discuss the option of corrective melatonin administration, usually 2 to 3 mg daily, before bedtime. The possibility that compensatory melatonin intake might interfere has yet to be investigated in a systematic manner. Close supervision and regular monitoring may be warranted if the option to coadminister melatonin is chosen.

Sedative Medications

Theoretically, concomitant use of sedative agents and oral melatonin may result in an additive effect and excessive central nervous system (CNS) sedation. Prudence suggests that such combinations be avoided outside the close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics.

NUTRIENT-NUTRIENT INTERACTIONS

Alcohol/Ethanol

Consumption of ethanol during the evening, in quantities comparable to typical social consumption, has been found to inhibit nocturnal melatonin secretion in a randomized, double-blind, crossover study involving healthy volunteers.[89] This observed depletion pattern might play a role in the sleep disturbances common to alcohol consumption, particularly on a chronic basis. Evidence is lacking to suggest that compensatory melatonin use might be beneficial or problematic.

Tryptophan

Tryptophan and melatonin synthesis and metabolism are intimately related, and tryptophan administration may help correct low-melatonin responses.

Vitamin B_6, Pyridoxine

A pyridoxine deficiency state may affect the tryptophan-serotonin-melatonin pathway and inhibit the synthesis of melatonin. Concomitant use of substances may be appropriate.

Vitamin B_{12}

Vitamin B_{12} can influence melatonin secretion, although evidence is mixed as to the character and degree of that effect, particularly in different populations and settings. Vitamin B_{12} may phase-advance the human circadian rhythm by increasing the light sensitivity of the circadian clock.[90]

The low vitamin B_{12} status of many elderly patients may be related to their levels of melatonin. The beneficial effects of melatonin on sleep-wake cycles may be enhanced by 1.5 mg of vitamin B_{12} (methylcobalamin) daily, presumably because of improved melatonin secretion.

HERB-NUTRIENT INTERACTIONS

Hypnotic Herbs

Some herbs used traditionally to induce or deepen sleep may have additive or synergistic interactions with melatonin. Physicians treating individuals choosing to combine melatonin with lemon balm *(Melissa officinalis)*, hops *(Humulus lupulus)*, valerian *(Valeriana officinalis)*, passiflora *(Passiflora incarnata)*, or similar herbs for the treatment of chronic or recalcitrant insomnia are advised to consult with or refer to health care professionals trained and experienced in botanical medicine and nutritional therapeutics. Proper diagnosis is always an essential prerequisite to any safe and effective treatment of a chronic condition.

The 90 citations for this monograph, as well as additional reference literature, are located under Melatonin on the CD at the back of the book.

Omega-3 Fatty Acids

Nutrient Name: Omega-3 fatty acids (ALA, DHA, EPA).
Synonyms: Alpha-linolenic acid (ALA), docosahexaenoic acid (DHA), eicosapentaenoic acid (EPA).
Synonyms, Collective: Essential fatty acids (EFAs); polyunsaturated fatty acids (PUFAs); omega-3s, n-3 fatty acids.
Fish Oils: Docosahexaenoic acid (DHA), eicosapentaenoic acid (EPA); cod liver oil; ethyl-omega-3 fatty acids.
Flaxseed and Flaxseed Oil *(Linum usitatissimum)*: Alpha linolenic acid, alpha-linolenic acid, ALA, type I flaxseed/flaxseed (51%-55% ALA), type II flaxseed/CDC-flaxseed (2%-3% ALA); alashi, brazen, common flax, flachssamen, flax, Graine de Lin, leinsamen, hu-ma-esze, Linaceae, linen flax, lini semen, lino, lino usuale, linseed, linseed oil, lint bells, linum, *Linum catharticum*, *Linum humile* seeds, kuten, sufulsi, tesi-mosina, winterlein.
Alpha-linolenic acid (ALA): Canola/rapeseed, eichium oil, hemp seed oil, perilla, purslane; fiber.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Angiotensin-converting enzyme (ACE) inhibitors ⊕⊕	Fish oil may decrease immunological renal injury in patients with IgA nephropathy and thereby slow the decline in renal function. Research has been limited and findings mixed. Significant adverse effects or interference with drug efficacy appear improbable.	Consider coadministration of fish oils with ACE inhibitors in IgA nephropathy to reduce renal damage and slow disease progression. Closely monitor high-risk patients.
Anticonvulsant medications (AEDs) ⊕⊕	Concomitant use of fish oil with anticonvulsant drugs may enhance therapeutic action through mediation of inflammatory processes, shifting fatty acid balance away from arachidonic acid, and other, more general effects. Preliminary findings indicate reduced frequency of seizures with low omega-3 oil dosages. Limited duration of benefits suggests need to investigate dose, form, and other issues of administration. Significant adverse effects or interference with drug efficacy appear improbable.	Consider coadministration of fish oil with AEDs. Dose varies according to patient characteristics. Food sources also advisable.
Chemotherapy Cytotoxic agents ⊕⊕/☼	Fish oil may benefit oncology patients in many ways, particularly by reversing decreased appetite and weight loss associated with both cancer and chemotherapy. Mechanisms are uncertain, but EPA and DHA can alter proinflammatory cytokine production and acute-phase protein synthesis, as well as mitigate oxidative damage and drug toxicity and protect healthy cardiac function, without reducing drug efficacy. Findings suggest type of cancer and disease stage can influence degree of benefit.	Consider incorporating fish oil into cancer treatment protocols for patients with or at risk for cachexia, to restore appetite and prevent or recover weight loss, particularly in patients with low fish intake. Food sources also advisable. Close monitoring appropriate.
Cyclosporine ⊕⊕/☼	Coadministration of fish oil during cyclosporine therapy may support kidney function and reduce hypertension without adversely affecting drug activity, rates of rejection, or graft survival. Diverse mechanisms are likely, with preservation of microvascular endothelial function being central. Evidence is mixed regarding degree of benefit to renal function but largely favorable.	Consider coadministration. Dose varies according to patient characteristics. Food sources also advisable. Closely monitor renal function.
Etretinate ⊕⊕	Addition of fish oil may enhance therapeutic efficacy of oral etretinate for patients with recalcitrant psoriasis. Adverse effects from fish oil are improbable, but drug has limited use since being banned in the U.S. and Canada. Studies and reports on possible interactions with similar drugs are not available, but synergy with acitretin (which replaced etretinate in the U.S. and Canada) seems likely, given the similarity between these oral retinoids.	Consider coadministration. Other pharmacological agents with a superior safety profile may be preferable.
HMG-CoA reductase inhibitors (statins) ⊕⊕	Fish oil and statin therapy can provide a synergistic effect in mixed dyslipidemias, particularly with integrative strategy combining healthy diet, regular exercise, and customized nutrient support program. While improving numerous vascular characteristics and predictably reducing triglycerides, fish oil administration may increase LDL levels and decrease glycemic control. These potential adverse effects	Fish oil is important to integrative treatment of dyslipidemias and prevention of cardiovascular disease. Known benefits on triglycerides can complement other agents; these may be required to counter potential LDL-elevating effects of fish oil.

Continued

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
	may be transient or related to patient-specific factors, but can be prevented with aerobic exercise and pectin fiber. Combination therapies to enhance risk reduction, increase therapeutic effect, and mitigate adverse effects may offer evolving and personalized options for cardiovascular care.	Support for exercise and healthy diet are central to any comprehensive program.
Selective serotonin reuptake inhibitor (SSRI) antidepressants ⊕⊕	Coadministration of fish oil, preferably with an increased proportion of DHA, may enhance therapeutic activity of antidepressant medications. Mechanisms not fully established but include critical role of EFAs in normal serotonin synthesis. Research limited and findings more often positive than not, but continued clinical trials anticipated. Adverse effects are improbable.	Combine with regular exercise, stress management, and healthy dietary changes for comprehensive approach. Ethyl ester or other preparation may be preferable. Food sources also advisable, particularly with prior low fish intake.
Sulfasalazine Corticosteroids, oral ⊕⊕/☼	Omega-3 fatty acids may reduce many symptoms of inflammatory bowel disease, especially through modulating inflammation, reducing oxidative stress, and altering phospholipid-membrane fatty acid composition. Concomitant therapy with sulfasalazine may exert multiple additive effects, particularly on balance between pro-oxidant and antioxidant mechanisms. Findings show effect on inflammation often limited, but consistent ability to reduce corticosteroid dose. Further research warranted.	Patients with inflammatory bowel conditions may benefit from omega-3 fatty acid monotherapy (ALA or fish oil) or as complement to sulfasalazine or other anti-inflammatory agents.

IgA, immunoglobulin A; *AEDs*, antiepileptic drugs; *LDL*, low-density lipoprotein; *HMG-CoA*, 3-hydroxy-3-methylglutaryl coenzyme A

NUTRIENT DESCRIPTION

Chemistry and Forms

Fish Oils: Docosahexaenoic acid (DHA), eicosapentaenoic acid (EPA); cod liver oil; ethyl-omega-3 fatty acids.

Flaxseed and Flaxseed Oil (*Linum usitatissimum*): Alpha linolenic acid, alpha-linolenic acid, ALA, type I flaxseed/flaxseed (51%-55% ALA), type II flaxseed/CDC-flaxseed (2%-3% ALA); alashi, brazen, common flax, flachssamen, flax, Graine de Lin, leinsamen, hu-ma-esze, Linaceae, linen flax, lini semen, lino, lino usuale, linseed, linseed oil, lint bells, linum, *Linum catharticum, Linum humile* seeds, keten, sufulsi, tesi-mosina, winterlien.

Alpha-linolenic acid (ALA): Canola/rapeseed, eichium oil, hemp seed oil, perilla, purslane; fiber.

Related Substances: DHA-45, ethyl-omega-3 fatty acids, Omacor; gamma-linolenic acid (GLA, as in borage, evening primrose, and black currant seeds), hemp seed oil, linoleic acid (LA), n-6 fatty acids, omega-6 fatty acids, omega-6s, omega-9s (from olive and macadamia nuts), vegetable oils.

Note: Omega-6 fatty acids are physiologically and clinically distinct and should not be confused with fatty acids of the omega-3 series.

Physiology and Function

The designation "omega" indicates at which position the first unsaturated (double) bond occurs at the noncarboxyl end of the molecule. Therefore, the first double bond in the omega-3 series is between the third and fourth carbon atoms, for the omega-6 series it is between the sixth and seventh carbon atoms, and for the omega-9 series, between the ninth and tenth carbon atom, from the noncarboxyl end of the molecule. There is no evidence that fatty acids from the omega-3, -6, and -9 series can be interconverted between series in the body.

Omega-3 fatty acids are essential to human physiology, particularly the immune system, circulatory system and central nervous system (CNS), and are obtained through foods and produced endogenously. Fish is the major dietary source of long-chain omega-3 polyunsaturated fatty acids (PUFAs), specifically the 20-carbon *eicosapentaenoic acid* (EPA) and the 22-carbon *docosahexaenoic acid* (DHA). Linoleic acid and linolenic acid are also essential fatty acids (EFAs). *Alpha-linolenic acid* (ALA) is an 18-carbon omega-3 polyunsaturated EFA that can serve as an essential precursor to both EPA and DHA. Humans are capable of synthesizing small amounts of EPA and DHA from ALA, but an as-yet undetermined dietary requirement of DHA and EPA is probable. Conversion of ALA by humans to the more active, longer-chain EPA and DHA is inefficient: less than 5% to 10% for EPA and less than 1% for DHA in men, whereas women can convert up to 9% of ALA to DHA, possibly because of the importance of DHA in fetal and infant nutriture.[1] Thus, total, ALA requirements may be higher for vegetarians than for nonvegetarians, because vegetarians must rely on conversion of ALA to EPA and DHA.[2] Algae-derived DHA supplements may also be an important nutrient source for vegetarians, particularly for men and weaned vegetarian children. EPA may be produced in vivo by beta-oxidation of DHA, although increased availability of algae-derived EPA supplements in the next few years is anticipated. Algae-derived omega-3 fatty acids will undoubtedly become increasingly important for nonvegetarians given the limited capacity of ocean fish stocks to sustain their populations in the face of increasing human demands and habitat destruction.

Linoleic acid, an EFA of the omega-6 series, which occurs naturally in many warm-weather vegetable oils, is the precursor of arachidonic acid (AA), which serves as substrate for inflammatory prostaglandins, thromboxane, and leukotrienes. Extensive research indicates that omega-3 fatty acids modulate inflammation and support healthy function of neural, cardiovascular, joint, and connective tissue. EPA modulates clotting and has a significant anti-inflammatory effect through its impact on prostaglandin metabolism.

The activity of omega-3 fatty acids in modulating immune function involves several important mechanisms. These oils

play pivotal roles in the resolution of inflammatory processes through modulation of proinflammatory and prothrombotic eicosanoid production (prostaglandins, thromboxane, and leukotrienes derived from AA) and reduction in interleukin-1 (IL-1) and other inflammatory cytokines. They are also directly involved in anti-inflammatory eicosanoid production. The partial replacement of AA with EPA in cell membrane lipids appears to play a key role in the activity and effects of omega-3 fatty acids. EPA acts as a substrate for the synthesis of the PG3 series of prostaglandins and increases production of these prostaglandins and thromboxane A_3 (TXA_3), which produce less inflammation than the PG2 series and TXA_2 (derived from AA), which they displace. Similarly, EPA acts as the source of series 5 leukotrienes, which have weaker inflammatory effects, while AA acts as the source of the more inflammatory series 4 leukotrienes. TXA_3, derived from EPA, is less potent in stimulating platelet aggregation than TXA_2, with attendant decrease in thrombotic risk. Furthermore, DHA inhibits the formation of the more inflammatory prostaglandins of the PG2 series, while EPA acts as a substrate for the synthesis of the less inflammatory prostaglandins of the PG3 series.

Fish oils benefit lipid metabolism and cardiovascular function through a variety of mechanisms not fully elucidated. Fish oils, by replacing other membrane fatty acids with omega-3 fats, improve blood flow characteristics, and also decrease platelet aggregation, all of which benefits individuals with atherosclerosis and at risk of clotting off a cerebral or coronary vessel. On the other hand, with individuals at risk for bleeding for other reasons, fish oils may slightly increase that tendency. The activity of EPA and DHA on peroxisome proliferator-activated receptor alpha (PPAR-α) appears to play a role in reducing triglycerides, modulating inflammatory reaction, and optimizing body composition.

These EFAs, particularly DHA, are highly concentrated in the brain's gray matter and retina and play a central role in neurological, cognitive, and behavioral development and function.[3,4] Brain cell membrane fluidity is essential for communication between neurons, and DHA helps maintain cell membrane fluidity as well as replenish brain tissue. Further, DHA supply in pregnancy affects placental expression of fatty acid transport proteins.[5] Consequently, infants who fail to receive adequate omega-3 fatty acids from their mothers during pregnancy are at increased risk for developing vision and CNS deficits.[6-8] Furthermore, deficiencies in DHA and EPA during early developmental stages, especially in infants deprived of DHA-rich breast milk, "may lower serotonin levels at critical periods of neurodevelopment and may result in a cascade of suboptimal development of neurotransmitter systems limiting regulation of the limbic system by the frontal cortex." Subsequently, the resulting deficits may produce residual developmental effects that "may be manifest as dysregulation of sympathetic responses to stress including decreased heart rate variability and hypertension, which in turn have been linked to behavioral dysregulation."[9] The full implications of these developmental perturbations and their significance in healthy function, dysfunction, and disease throughout childhood and adulthood have only begun to be understood.[8,10-12]

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Omega-3 Fatty Acids

Angina, amyotrophic lateral sclerosis (risk reduction), arthritis, artherosclerosis, asthma, bipolar disorders, breastfeeding support, cancer, cardiovascular disease, cholesterol, chronic obstructive pulmonary disease (COPD), colon cancer, Crohn's disease, cystic fibrosis, depression, diabetes mellitus, dysmenorrhea, eczema, endometriosis, glaucoma, human immunodeficiency virus and acquried immunodeficiency syndrome (HIV/AIDS) support, hyperlipidemia, hypertension, hypertriglyceridemia, immune support, inflammatory bowel disease, mental disorders, migraine, multiple sclerosis, myocardial infarction, neonatal development, nephropathy, neurodegenerative disease, osteoarthritis, osteoporosis, phenylketonuria, photosensitivity, preeclampsia, pregnancy and postpartum support, presurgical and postsurgical support, psoriasis, Raynaud's syndrome, rheumatoid arthritis, sickle cell anemia, sudden cardiac death (risk reduction), systemic lupus erythematosus (SLE), ulcerative colitis.

EPA and DHA (Long Chain Omega-3s)

Acute myocardial infarction, acute respiratory distress syndrome (ARDS), age-related macular degeneration, aggressive behavior, agoraphobia, Alzheimer's disease, angina, anorexia nervosa, anthracycline-induced cardiac toxicity, anticoagulation, antiphospholipid syndrome, anxiety, arthritis, arthrosclerosis, asthma, attention deficit–hyperactivity disorder (ADHD), autoimmune nephritis, Behçet's syndrome, bipolar disorder, borderline personality disorder, breast cancer risk, breastfeeding support, burns, cachexia during chemotherapy, cancer treatment support, cardiovascular disease prevention, chronic fatigue syndrome, chronic obstructive pulmonary disease (COPD), cirrhosis, colorectal cancer risk, Crohn's disease, cystic fibrosis, dementia, depression, dermatomyositis, diabetes mellitus type 1, diabetes mellitus type 2, diabetic nephropathy, diabetic neuropathy, dyslexia, dyslipidemia, dysmenorrhea, dyspraxia, eczema, emphysema, endometriosis, exercise performance enhancement, fibrocystic breasts, gallstones, gingivitis, glaucoma, glomerulonephritis, glycogen storage diseases, gout, hepatorenal syndrome, human immunodeficiency virus and acquired immunodeficiency syndrome (HIV/AIDS) support, hypercholesterolemia, hyperlipidemia, hypertension, hypertriglyceridemia, hypoxia, ichthyosis, immune function, immunosuppression, inflammatory bowel disease, leprosy, leukemia, Lyme disease, malaria, male infertility, mastalgia, memory enhancement, menopausal symptoms, menstrual cramps, mental disorders, migraine, multiple sclerosis, myopathy, neck and low back pain, neonatal development, nephrolithiasis, nephropathy, neurodegenerative disease, neuropathy, night vision enhancement, obesity, omega-3 fatty acid deficiency, osteoarthritis, osteoporosis, panic disorder, peripheral vascular disease, phenylketonuria, photodermatitis, photosensitivity, postviral fatigue syndrome, preeclampsia, pregnancy and postpartum support, premature birth prevention, premenstrual syndrome, presurgical and postsurgical support, prostate cancer prevention, psoriasis, Raynaud's phenomenon, Refsum's syndrome, retinitis pigmentosa, Reye's syndrome, rheumatoid arthritis, schizophrenia, seizure disorder, sickle cell anemia, stroke prevention, sudden cardiac death (risk reduction), suicidal tendencies, systemic lupus erythematosus (SLE), tardive dyskinesia, tennis elbow, urolithiasis, ulcerative colitis, vision enhancement.

Alpha-Linolenic Acid (ALA)

Breast cancer, cardiovascular disease, diabetes mellitus, eczema, hypercholesterolemia, hyperlipidemia, hypertension, hypertriglyceridemia, laxative, lupus nephritis, menopause, menstrual breast pain, prostate cancer, psoriasis.

Deficiency Symptoms

Dry scaly skin, hair loss, immune system insufficiency, inflammation, poor wound healing; impaired vision, reduced childhood growth and impaired brain and eye development.

Dietary Sources

Alpha-Linolenic Acid (ALA)

Canola (rapeseed) oil, eggs (from hens fed flaxseed), hemp seed oil, echium seed oil, flaxseed (linseed), perilla seed, pumpkin seed, purslane, walnuts, wheat germ.

Note: Safflower, sesame, and sunflower, and to a lesser degree soybean, contain ALA but also contain countervailing omega-6 fatty acids in significantly higher amounts.

DHA and EPA

Fish, fish oil; eggs (from hens fed DHA-rich algae); infant formula; margarine and milk fortified with EPA/DHA.

Fish oils and plant oils are the primary dietary sources of omega-3 fatty acids. The omega-3 fatty acids DHA and EPA are the key constituents in the oil found in cold-water fish. The high concentrations of omega-3 fatty acids in these fish may result from its "antifreeze" property. The richest sources of naturally occurring omega-3 oils include salmon, mackerel, halibut, sardines, and herring. The preparation of fish also influences its physiological and therapeutic actions, with "intake of tuna or other broiled or baked fish being associated with improved cardiac hemodynamics, but fried fish intake being associated with structural abnormalities indicative of systolic dysfunction and potential coronary atherosclerosis."[13] The liver of the cod, halibut, or shark is the primary source of fish liver oil, whereas herring, sardine, salmon, or anchovy flesh usually serves as the source of fish body oil. Other food from the oceans can also provide omega-3 oils. Some marine phytoplankton (microalgae) are good sources of DHA and can be obtained as nutritional products. New Zealand green-lipped mussels *(Perna canaliculus)* also contain omega-3 fatty acids and have been consumed by the Maori people of the South Pacific for centuries.[14] EPA/DHA has been added to "fortify" some foods, such as eggs, bread, margarines, and milk. Oil extracted from ocean krill (zooplankton) is also a rich source of EPA and DHA, available as a nutritional supplement, and in which EPA and DHA are uniquely bound in phospholipids, rather than triglycerides as in fish body/liver oils.

Fish liver oil, but not fish body oil, is also rich in vitamins A and D. For example, cod liver oil liquids normally provide concentrations of 750 to 1200 µg (2500-4000 units) vitamin A per 10 mL and 2.5 to 10 µg (100-400 units) vitamin D per 10 mL, although there is significant variability between brands, depending on multiple factors, including region, time of year, and processing. These vitamins are even more concentrated in halibut and shark liver oils. Shark liver oil is also rich in compounds called alkoxyglycerols, which are reputed to have protective effects from radiation therapy.[15,16] Oil from both body and liver of fish also contains some vitamin E.

Although they are readily available in many common foods, the ability to convert omega-3 fatty acids from vegetable sources to EPA within the human body is quite limited. ALA is found in a variety of plant foods, especially canola (rapeseed) oil, flaxseeds, flaxseed oil, pumpkin seeds, pumpkin seed oil, purslane, perilla seed oil, soybeans, soybean oil, walnuts, and walnut oil.

Nutrient Preparations Available

Fish oil products usually contain vitamin E and other antioxidant nutrients to reduce oxidative degradation and rancidity; this inherent problem may also be mitigated by extracting the oxygen from the capsule. Long-term intake of fish oil could theoretically cause a deficiency of vitamin E by increasing oxidative stress on fat-soluble antioxidants. Consequently, many commercial fish oil products contain additional vitamin E, which also acts as an antioxidant to prevent rancidity before ingestion.[17]

Variations on usual fish oil products have been developed for special populations. Fish oil preparations emphasizing DHA and containing no or lesser proportions of EPA are sometimes used with infants (or others) who generally do not need EPA. Enteric-coated, free–fatty acid preparations of purified EPA/DHA derived from fish oil are sometimes preferable for patients with Crohn's disease or other gastrointestinal (GI) conditions because of their reduced tendency to cause digestive distress. Omega-3 fatty acid ethyl esters are a slightly modified form of fish oil approved by the U.S. Food and Drug Administration (FDA) as a prescription treatment for hypertriglyceridemia either as monotherapy or in combination with statins or fibrates.[18]

Both EPA and DHA can be obtained from various algae. DHA-45 is an innovative proprietary source of DHA produced through a multistep fermentation and refining process using a nonpathogenic marine protist. The final product consists of approximately 45% DHA and is intended for use in food, but safety has not been fully established.[19] Martek produces DHA from cultured microalgae for use in infant formula and DHA products. Several European companies are planning to produce both EPA and DHA from algae, although at the time of this writing, these are not yet commercially available.

Flaxseed, flaxseed oil, and fish oil require refrigeration to maintain their integrity, even though many encapsulated fish oil products are stable at room temperature. Whole flaxseeds need to be consumed within 24 hours of being ground, or their unsaturated fatty acid constituents degrade through oxidation.

Dosage Forms Available

Fish oil: Capsule, gel cap, oil (liquid, often flavored with citrus or other fruit oils).
Flaxseed: Oil (liquid), powder, whole seeds.

For fish oil preparations, dosing should be based on the amount of EPA and DHA (omega-3 fatty acids) in a product, not on the total amount of fish oil. Commercial products vary in the amounts and ratios of EPA and DHA. A common amount of omega-3 fatty acids in fish oil capsules is 0.18 g (180 mg) of EPA and 0.12 g (120 mg) of DHA per gram of oil. Five grams of fish oil contains approximately 0.17 to 0.56 g (170-560 mg) of EPA and 0.072 to 0.31 g (72-310 mg) of DHA. Different types of fish contain variable amounts of omega-3 fatty acids; likewise, different types of nuts or oil contain variable amounts of ALA.

Flaxseed can be administered in several forms, as an oil in liquid medium or capsule, ground into powder, or mixed with liquid. See dosage section for further details.

Source Materials for Nutrient Preparations

Fish oil can be derived from a wide variety of fish species, each with different amounts and relative proportions of EPA and

DHA.[20] DHA and EPA are also commercially derived from both wild and cultivated algae.

Alpha-linolenic acid (ALA) can be obtained from a variety of nuts and vegetable oils, including canola oil, flaxseed/linseed oil, flaxseeds, olive oil, soybean oil, walnut oil, walnuts (English).[20]

Dosage Range

Optimal dosage has not been established. Over-the-counter (OTC) products typically provide 200 to 1500 mg combined EPA/DHA per dose. Clinical trials investigating fish oil therapeutics have often used 3 to 4 g daily (EPA/DHA), but doses of 1 to 2 g may be adequate, depending on the clinical application.

Dietary

Adult. No daily requirement for fish oil or EPA and DHA has been established. The adequate intake (AI) for ALA has been established as 1.6 g per day for men and 1.1 g per day for women. AIs represent the least amount needed to deter deficiency but do not take into account disease prevention. A healthy diet should provide at least 5 g total essential fatty acids daily. The dietary intake of omega-3/omega-6 fatty acids of most individuals is typically both low and imbalanced. The average American diet contains approximately 1.6 g omega-3 fatty acids per day, of which only 0.1 to 0.2 g comes from EPA and DHA and approximately 1.4 g (~90%) from ALA. Moreover, in Western diets, except for specific populations with unusually high fish intake, consumption of omega-6 fatty acids is about 10 to 40 times greater than that of omega-3 fatty acids. This high proportion of omega-6 fatty acid intake results largely from the widespread use of vegetable oils containing linoleic acid, a relatively recent dietary development, historically speaking. Increasing omega-3 fatty acid intake or decreasing intake of omega-6 fatty acids can improve the ratio, as well as health benefits, because omega-6 and omega-3 fatty acids compete for conversion into active metabolites.

The American Heart Association recommends that healthy adults with no history of heart disease eat fish at least twice weekly, preferably broiled or baked, not fried.[21] Fatty fish, in particular, are superior sources; these include anchovies, bluefish, carp, catfish, halibut, herring, lake trout, mackerel, pompano, salmon, striped sea bass, tuna (albacore), and whitefish. However, some fish need to be consumed in limited amounts because they contain high levels of mercury and other toxins. Swordfish, king mackerel, shark, and tilefish should be limited to 7 ounces per week (and avoided by pregnant women); tuna and red snapper should be limited to 14 ounces per week; salmon, catfish, mahi mahi, and canned tuna have no established restrictions. Consumption of plant-derived sources of ALA, such as tofu/soybeans, walnuts, flaxseed oil, and canola oil, is also recommended, although some experts have reservations about the euricic acid content of canola oil, which is a potentially problematic, very-long-chain fatty acid. Various national regulatory agencies, as well as the World Health Organization (WHO), recommend a daily dietary intake of 0.3 to 0.5 g EPA plus DHA and 0.8 to 1.1 g ALA (although this latter value is somewhat below the AI established for ALA).

Pregnancy and Nursing. Pregnant and lactating women are often advised to consume sufficient fish oils to provide at least 300 mg DHA daily to promote healthy neural and optical development in the child. Adequate DHA intake during pregnancy has also been associated with a decreased risk for postpartum depression.

Infants and Children. Although widely recognized for its critical role in development, no therapeutic protocols or standards of treatment have been established for the use of fish oils such as DHA by infants or children. An ample supply of DHA and AA enable healthy neurological and retinal development in infancy. Breast milk and brain tissue exhibit the highest naturally occurring concentrations of EPA and DHA in the human body, and breast-fed infants exhibit higher concentrations of erythrocyte DHA and AA than bottle-fed infants, with corresponding increases in visual acuity and developmental tests (vs. bottle-fed counterparts).[8,22] Infant formula is required by law in most developed countries; except the United States, to contain DHA. Formula should contain 0.35% DHA and less than 0.1% EPA.

ALA content in breast milk depends on maternal diet and may be adequate with proper nutrition, but it can vary considerably. Maternal intake of flax oil or fresh-ground seed can be used to increase ALA content in breast milk. Infant formula should contain 1.5% ALA.

A child's fatty acid intake may be enhanced and balanced through addition of freshly ground flaxseeds and flaxseed oil.

Supplemental/Maintenance

The recommendation for fish oil preparations is 3000 to 4000 mg fish oil per day, which is equivalent to approximately two to three servings of fatty fish per week. A single 1000-mg fish oil capsule typically contains 180 mg EPA and 120 mg DHA.

Supplementation is not necessary in children who are breast-fed because breast milk contains adequate amounts, assuming adequate maternal dietary intake. Infants not being breast-fed and other children can benefit from omega-3 fatty acids, but dosage levels have not been established. Exogenous DHA administration can increase levels of DHA in breast milk, and higher breast milk DHA levels increase the DHA in infants' cell membranes.[23-25] The metabolism of infants appears to have minimal need for EPA.

A typical dose for flaxseed can range from 1 tablespoon two to three times daily to 2 to 4 tablespoons once daily; usually ground and consumed with water; 100 g raw flaxseed provides 22,800 mg ALA.

Flaxseed oil can be dispensed in a liquid form, with a 15-ml tablespoon containing approximately 7 g ALA. A dose of 1 or 2 tablespoons of flaxseed oil daily is appropriate as a general recommendation. Refrigeration is essential to stable storage; integrity is significantly compromised with heating because of rapid oxidation of unsaturated bonds.

Flaxseed oil can also be distributed in a capsule form, with a typical 1000-mg capsule providing 500 mg ALA. Oral consumption of raw flaxseeds in doses up to 50 g daily for up to 4 weeks has been reported. Oral doses of 10 to 60 g daily have been used in several studies for periods of less than 2 weeks. A dose of 50 g flaxseeds is roughly equivalent to 250 g flaxseed flour.

Doses of soluble flaxseed mucilage/fiber as high as 60 to 80 g/kg body weight have been administered in research settings.

Pharmacological/Therapeutic

The appropriate range for an effective dose of omega-3 oils, regardless of the form or source, is under debate. Dosage suggestions in the literature range from 1 to 10 g per day. However, the appropriate dosage varies depending on the pathophysiology in question and the level of health in a given individual.

A maximum tolerated dose of 0.3 g/kg/day of fish oil capsules has been proposed; this tolerance is equivalent to 21 1-g capsules daily for a 70-kg (154-lb) patient.[26] Typical dosages of fish oil in therapeutic settings range from 3 to 9 g daily, but this is not the upper limit, and dosages in oncological settings are often 12 to 15 g/day, or more. Subjects in one clinical trial ingested 60 g daily. In essence, matching the dosage used in several major studies would require fish oil adequate to supply about 2 to 3 g EPA (2000-3500 mg) and about 1.0 to 2.5 g DHA (1000-2500 mg) daily. However, much higher doses have been used in some studies. The U.S. FDA classifies intake of up to 3 g/day omega-3 fatty acids from fish as "generally regarded as safe" (GRAS).

Children (2-12 years). Daily administration, typically about 1 teaspoon daily of ground flaxseeds or 1 teaspoon of fresh flaxseed oil, is often used in treating children with constipation.

Toxic. In their natural-occurring food contexts, omega-3 fatty acids possess an excellent safety profile and are considered generally nontoxic, particularly with single-dose or short-term application. Omega-3 fatty acids in OTC forms (i.e., free from contaminants) do not exhibit toxic levels in most individuals when used at standard doses. One study involving oncology patients being treated with concomitant fish oils for cachexia proposed a maximum tolerated dose of 21 g/day.[27] No maximum tolerated dose has been established for the general population or patients diagnosed with other conditions. However, the qualified health claim (for prevention of coronary heart disease) allowed for EPA/DHA by the FDA sets a maximum recommended intake of 2 g total EPA and/or DHA and suggests a maximum of 1 g, or about 3 g of usual-strength fish oil.

Contaminants do change the situation for many consumers of fish because methylmercury and other pollutants can represent significant health risks, especially in pregnancy, during breastfeeding, and throughout childhood development. Such contaminants are much less significant in fish oil products than with dietary consumption of fish meat.

Excessive intake of cod liver oil carries a risk of inducing vitamin A excess and thus is generally not considered a preferred source of EPA/DHA for long-term use. However, intakes of more than 1 ounce daily are necessary to provide excessive levels of vitamin A for most products. It would require extremely high intakes of fish liver oils to provide excessive intakes of vitamin D (>10,000 IU/day).

Laboratory Values

No clinical standards for laboratory evaluation of omega-3 fatty acid status have been established.

Fatty Acids, Nonesterified

Circulating nonesterified–fatty acid concentration is an independent factor for cardiac risk, especially sudden death in middle-aged men.[28] Omega-3 fatty acids are "preferentially stored in the Sn-2 position, from which they can be specifically and rapidly released by activated phospholipase A-2." However, free–fatty acid levels in plasma do not reliably reflect the immediate dietary consumption of fat because they primarily derive from the regulated turnover of lipid stores in adipose tissue by lipolysis and from phospholipids by phospholipases.[29]

Fatty Acid Composition of Serum Cholesterol Esters, Free Fatty Acids, Phospholipids, and Triglycerides

Blood levels of long-chain n-3 fatty acids have been used in clinical trials investigating the effects of omega-3 fatty acid intake.[30,31] Such assays are not usually applied in routine clinical settings, although they are incorporated in various risk profile panels used by health care professionals specializing in nutritional therapeutics.

Red Blood Cell Membrane Fatty Acid Composition

Measurement of long-chain omega-3 fatty acids in red blood cell (RBC) membranes is a sensitive indicator of deficiency but remains investigational. This measurement has been used as an indicator of cardiac risk and other related susceptibility.[31] Low levels indicate deficiency, but specific reference ranges vary among laboratories.

Serum (or Plasma) Phospholipid

Fatty acid analysis of phospholipid concentration in serum (or plasma) may provide a useful biomarker for assessing nutritional status and EPA/DHA intakes in relation to potential risk.[32,33] Resulting data can then be presented as an "omega-3 fatty acid profile" with both an omega-3 score and a DHA score.

SAFETY PROFILE

Overview: Fish Oil

Fish oil intake is generally considered to be well tolerated with an excellent safety profile.[19,34] Few clinically significant adverse effects have been reported. Studies investigating the maximum tolerated dose and dose-limiting toxicities of fish oil found GI complaints, mainly nausea, loose stools, or diarrhea, as the predominant adverse effects. In clinical practice, fish-flavored aftertaste and eructations represent the adverse effects most often mentioned by patients using fish oils. Various clinical trials have suggested possible adverse effects from fish oil intake in specific patient populations.

The preeminent issue of toxicity affecting fish oils results not from the nutrients themselves but from damage to the fish and the environment in which they develop. Fish oils are free of intrinsic risks in their native state. However, growing concerns are widely expressed over the effects of pollution, especially the presence of mercury, toxic organochlorines, and polychlorinated biphenyls (PCBs) in seafood and large fish in particular, both directly (for humans, sealife, and the planet) and in effects on fish oil products.

In particular, fish meat may contain methylmercury, pesticides, and heavy metals, and caution is especially warranted in pregnant and lactating women and young children.[34] Methylmercury is known to cause neurological and developmental disorders.[35,36] Fish oils derived from wild fish are generally considered less likely to contain significant amounts of mercury and other heavy metals, although this is ultimately a relative safety factor because these toxic materials have permeated the environment to some degree. Moreover, methylmercury tends to accumulate more readily in fish meat than in fish oil. Consequently, fish oil products have generally been found to be largely free of mercury; a process known as ***molecular distillation*** is required for reliable removal of PCBs and other toxic pollutants. Unrefined fish oil preparations may still contain pesticides or other pollutants. Thus, products that are assayed for peroxides and environmental contamination are recommended. Overall, the significant risks associated with fish oil consumption, through dietary and nutraceutical sources, derive from contamination rather than from the nutrients themselves and, in fact, are generally more problematic in fish than in fish oil products.

The loss of biodiversity and destruction of ocean ecosystems constitute the other side of the fish contamination issue. Overfishing, destructive fishing practices, and destruction of

habitats all represent huge problems reaching critical proportions.[37,38] Without significant and concerted global efforts to reverse these trends and establish sustainable practices, the availability of fish or omega-3 oils derived from fish may become obsolete and irrelevant. Advocating regular consumption of fish in the diet or products containing omega-3 fatty acids derived from fish on a global basis is unrealistic and inadvisable over the long term. Other technologies, such as those involving use of microalgae cultures, warrant aggressive research and rapid deployment.

Nutrient Adverse Effects

Eructations, nausea, dyspepsia, reflux, abdominal bloating and discomfort, flatulence, loose stools, diarrhea, and other minor GI complaints represent the most common adverse effects reported in individuals consuming fish oil products at typical levels, appearing in 1.5% to 5% of study subjects; severe diarrhea has been reported on rare occasions with the ingestion of high doses of fish oil supplements.[39,40] GI effects can be minimized if fish oils are taken with meals and if doses are started low and gradually increased; time-release preparations may also mitigate these complications. Such effects are generally considered improbable or inconsequential with dietary consumption of fish.

Caution should be used in regard to the dose of cod liver oil because of high vitamin A and D content. Large doses of vitamin A, particularly with rapid introduction, can be hepatotoxic (>20,000 IU/day combined with other hepatotoxic stress, e.g., chronic acetaminophen or alcohol use). Generally, the potential risk from vitamin D is considered greater in summer than in winter or cloudy climates, but this advisory may change given the emerging knowledge of pervasive vitamin D deficiency and insufficiency, versus previously dominant fears of vitamin D excess and toxicity.

The potential hematological effects of omega-3 fatty acids pose some of the more clinically significant effects in terms of unintended effects and interactions. Omega-3 fatty acids have multiple antithrombotic effects that may exert a bimodal effect (beneficial or adverse) depending on the individual, his or her physiology and medical conditions, and interactive medication effects. In particular, fish oils may decrease platelet aggregation, increase fibrinolysis, prolong bleeding time, and diminish von Willebrand factor, all of which concomitantly decrease thrombotic risk and increase bleeding risk. Daily doses of more than 3 g omega-3 fatty acids (9 g usual-strength fish oil) may increase the risk of bleeding, but there is a paucity of evidence to substantiate concerns of clinically significant bleeding risk at lower doses in most individuals.[47-49] Very high doses of omega-3 fatty acids in the form of fish oil, and at the intake level typical of indigenous Eskimo diet, could theoretically increase the risk of hemorrhagic stroke.[50] High-dose intake has also been associated with epistaxis and hematuria, usually in association with other anticlotting agents such as antiplatelet agents, as well as anticoagulants such as warfarin, or heparin.[51] Notably, in at least one study, hemostatic effects (opposite of increased bleeding risk) observed with dietary fish were not seen with fish oil products.[41] High levels of long-chain omega-3 fatty acids from marine sources reportedly may increase levels of plasminogen activator inhibitor type 1 (PAI-1), thus inhibiting endogenous fibrinolysis, with the attendant theoretical effect of increasing thrombotic risk. However, after careful assessment of this issue, Hansen et al.[52] concluded that, although dietary fat of any type somewhat raises PAI-1 levels, there is no difference between the long-chain omega-3 oils and any other type of fat in this regard.

Fish oil can play an important role in a strategic approach to treatment of individuals with dyslipidemias, hypercholesterolemia, and dermatitis. Dose-dependent elevations in low-density lipoprotein (LDL) levels of 5% to 10% have been observed with increased intake of 1 g or more daily of omega-3 fatty acids, with more substantial elevations in individuals with familial combined hyperlipidemia.[53] However, these LDL-raising effects were not observed in all trials and appear to be transient, and a paradoxical LDL-lowering effect may be seen at high doses (e.g., 32 g fish oil daily).[41,43,54-57] Furthermore, coadministration of pectin or garlic may counteract this possible adverse effect.[58,59] Isolated reports indicate that mild elevations in alanine transaminase (ALT) levels may occur.[60] Although fish oils are often used in the treatment of inflammatory skin conditions, skin rashes have been reported on rare occasions.[54,61]

In one rodent study, omega-3 fatty acids were associated with metastatic progression of colon cancer.[62] Consequently, concerns have been raised about use of omega-3 fatty acids, through dietary sources or nutraceutical products, in patients with advanced stages of colorectal cancer. The majority of animal studies, however, have indicated an overall anticancer effect of dietary long-chain omega-3 fatty acids.

Adverse Effects Among Specific Populations

Individuals with allergy or hypersensitivity to fish, seafood, or nuts may react to omega-3 fatty acid or ALA products derived from these substances. Checking labeling and avoiding potentially problematic substances are advised.

Hypomania has been reported in patients with bipolar disorder or major depression after use of omega-3 oils.[63] Clinical studies, however, have shown a beneficial effect in both bipolar disorder and depression.[64-70] Rare reports of restlessness and formication (sensation of ants crawling on the skin) suggest the need for vigilance when introducing therapeutic agents in any case involving a psychiatric diagnosis.

Elevations in blood glucose levels have been reported with daily doses of fish oil greater than 3 g for extended periods. The frequency and severity of the potential risk of increased or unstable blood glucose levels appear to be of concern primarily in individuals with diabetes or hypertriglyceridemia, but research has not elucidated a clear and consistent understanding of this observed phenomenon. Addition of vitamin E or regular aerobic exercise (½ hour three times per week) may mitigate this possible potential impairment of glucose tolerance.[51,71,72]

Contraindications

An increased death rate in the fish oil–administered group was observed in a single study involving patients with implanted cardiac defibrillators.[73] In contrast, observations and trials conducted in the United States and Europe indicate that the predominant effect of high omega-3 consumption (e.g., 1000 mg daily from fish oil) is a reduction in risk of sudden cardiac death.[74,75]

Potential effects on female hormones have occasionally led to statements that the use of flaxseed or flaxseed oil during pregnancy and breastfeeding is contraindicated.[76] Evidence from clinical trials or qualified case reports is lacking, but animal studies have suggested possible adverse effects.

Precautions and Warnings

Patients being treated for cardiac arrhythmias, particularly with a history of sustained ventricular fibrillation or ventricular tachycardia, require close supervision when introducing fish oil preparations into their therapeutic regimen or significantly altering the dose or form. Complex and often bimodal responses are possible and vary depending on source (fish vs. fish oils), dose, and patient characteristics. For example, although some research indicates that individuals who ate fish had a reduced risk for developing atrial fibrillation, preliminary data suggest that a high level of fish consumption (five or more servings per week) is associated with an increased risk of atrial fibrillation in middle-age men.[77] However, fish consumption also protects against ventricular fibrillation and sudden cardiac death and helps to protect the coronary vessels.

Likewise, similar cautions are relevant in patients with hypertension, diabetes, or other cardiovascular disease. Although omega-3 fatty acids may be beneficial for many individuals with these conditions, regular monitoring and close supervision are appropriate when introducing any nutraceutical or pharmacological agent, altering dose or form, or interjecting new medications that might interact with the nutrient or comedications.

Individuals with familial combined hyperlipidemia may exhibit an increased incidence of spontaneous bleeding.[48,78]

Coincident ingestion of fat-soluble vitamins, specifically vitamins A, D, and E, can unintentionally elevate these levels through use of fish oil products. Attention to labels and cumulative dose is important to avoid adverse effects, although frank toxicity caused by supplemental intake at typical doses is unlikely, except in cases of regular use of fish liver oils. These oils are particularly rich in vitamins A and D, the concentrations of which can vary widely between products, depending on source of fish liver and processing of the product.

INTERACTIONS REVIEW

Strategic Considerations

The physiological, preventive, and therapeutic effects of omega-3 fatty acids are overwhelmingly positive, and most interactions between this nutrient class and conventional pharmaceutical agents are beneficial. Although not quite the panacea predicted by many early enthusiasts, the breadth of research into and possible clinical applications of fish oils (DHA, EPA) and ALA has grown at an astounding pace in the past few decades. These "discoveries" not only point to the fundamental and multifactorial roles that omega-3 fatty acids play in many aspects of human physiology, but also highlight the deficits and imbalances in the human diet in developed societies. Moreover, the manifold mechanisms by which omega-3 fatty acids support and modulate many physiological functions, while introducing few significant adverse effects, make them a particularly appropriate agent for integration with a broad range of pharmaceutical agents, particularly those that treat or increase oxidative damage or inflammation, neuroendocrine or immune dysregulation, or cardiovascular dysfunction. Recommendation of two or more servings of fish rich in omega-3 oils per week has become standard within conventional medicine and governmental policy, but clinical application of the benefits of fish oil and ALA in nutraceutical forms has yet to be integrated into conventional practice guidelines.

Research into the physiology and therapeutics of long-chain omega-3 fatty acids has grown steadily ever since Bang and Dyerberg reported the association between a diet rich in long-chain marine omega-3 fatty acids and reduced incidence of atherosclerotic heart disease in Greenland Eskimos.[79-81] However, the epidemiological associations of dietary fish intake and therapeutic effects (or risks) of omega-3 fatty acids and fish oil in the subsequent decades of literature are often intertwined and mixed without clarity or consistency in analyses and conclusions.[57,82] Most importantly, many key variables need to be taken into account in study design, in presentation of findings, and in dissemination of news. Variables such as proportions of preintervention dietary constituents, differentiation of dietary fish rich in omega-3s versus less oily fish, proportions of EPA and DHA in different preparations, and methods of extraction and purification can significantly alter findings and their clinical implications. However, these factors frequently are inadequately factored into meta-analyses, reviews, and news reports in both professional publications and the lay press.

The role of fish oil in development of the CNS and subsequent neurological and cognitive function is generally accepted.[83-88] In particular, DHA is pivotal through its activity as a major component of the phospholipid layer of neuronal membranes. Its roles in chloride and other ion channel opening at the synapse of neurons, increasing stability of neuronal functioning, influencing multiple gene expressions, modulating GABA responses, promoting dopamine and serotonin neurotransmission, increasing acetylcholine release, inhibiting multiple spikes in epileptiform activity, protecting against oxidative stress, and serving as an overall neuroprotectant, place DHA, and to a lesser extent its shorter-chain sibling EPA, at the center of ongoing and evolving neurocognitive science.[89-96] Surprisingly, however, the medical literature still contains lingering hesitations regarding the universal efficacy of increasing DHA during pregnancy and infant nutrient intake. In these areas the incomplete and sometimes contradictory evidence regarding the preventive properties of fish oil remains a source of controversy and investigation. Further research into the important supportive role of fish oil throughout the life cycle, from embryonic and infant development to preventing dementia in the elderly, continues to emerge, and the only remaining question is the degree to which conventional medicine can integrate this important nutritive strategy.

A broad consensus supports the proposition that fish and marine omega-3 fatty acid intake is associated with improved cardiovascular health. The central role of fish oil in risk reduction, prevention, and treatment of cardiovascular disease derives from broadly accepted functions and activities, including effects on inflammation and oxidation, membrane physiology and lipoprotein metabolism, blood vessel pliability and atherosclerotic plaque formation, platelet reactivity, and blood flow characteristics. Nevertheless, the efficacy and safety of fish oil administration for heart disease in general and patients with particular conditions remain controversial and uncertain, with data and interpretations suggesting a range of responses, from beneficial to potentially dangerous; some commentators interpret these contradictory findings to suggest that fish oil's benefit to individuals with heart disease is slight or nonexistent.[97-99] Consequently, according to various sources, fish and fish oil may reduce the risk, incidence, and severity of atherosclerosis, thrombosis, arrhythmias, atrial fibrillation, coronary heart disease, sudden cardiac death, heart failure, and stroke or may, on the other hand, potentially increase risk of sudden death from myocardial infarction in individuals with stable heart disease.[97,99-101] Nevertheless, in a review of data on the efficacy and safety of different antilipidemic agents and diets on mortality, Studer et al.[102] found that fish oil is superior to statin therapy for lowering overall cardiac mortality risk. They also found,

regarding the fibrate class of antilipidemics (which historically preceded the statins), "any potential reduction in cardiac mortality from fibrates is offset by an increased risk of death from noncardiovascular causes."[102]

In addition to nutritive, antioxidant, and inflammatory modulation effects, the known antithrombotic effects of omega-3 fatty acids on platelet aggregation and blood viscosity suggest that administration may be beneficial in conjunction with surgical procedures such as prevention of restenosis after coronary angioplasty (PTCA) or prevention of graft failure after heart bypass surgery. Analyzing electrocardiographic (ECG) data from two prospective trials that included 52 heart transplant recipients, Harris et al.[103] found that administration of 1 to 3.4 g omega-3 fatty acid daily for 4 to 6 months reduced heart rates and prolonged QRS duration, even though these patients were presumably devoid of vagal innervation, suggesting that n-3 fatty acids may modify electrophysiological properties of the myocardium itself. Research into such integrative approaches, however, is still emerging and inconclusive, with findings that have been mixed and often less positive than expected.[46,104-109]

The potential small increase in bleeding risk, possibility of elevated LDL cholesterol level, and impact on glycemic control constitute the primary adverse effects consistently appearing in the literature, besides nausea, loose stools, and fishy eructations. These effects, however, are often transient, dose dependent, and preparation related and can usually be corrected by regular exercise and increasing dietary fibers such as pectin, especially within the context of a comprehensive strategy integrating lifestyle changes, improved diet, stress management, conventional medications, and specific nutrient/herb combinations.[59,72] Such synergistic approaches can be personalized and can evolve in response to the initiative and abilities, risks and needs, and susceptibilities and tolerances of the individual patient. As with other intersections of body systems and pathophysiology, individual pharmacogenomic variability, patient participation and compliance, and the therapeutic relationship play highly influential roles in determining risk severity, medication reactions, and therapeutic response. Although issues regarding potential for increased bleeding risk at high doses and possible elevation of LDL cholesterol level or reduced glycemic control will remain cause for concern and monitoring, these adverse effects are not axiomatic, universal, severe, or irremediable.

A review of the scientific and medical literature reveals broad support, with a strong and consistent underlying body of scientific evidence, for regular dietary intake of omega-3 fatty acids in amounts greater than currently in common use, with an accompanying reduction in omega-6 fatty acid intake (predominantly from warm-weather vegetable oils and grains) and a preferred emphasis on dietary fish consumption. The issue of shifting the balance between omega-3 and omega-6 fatty acids remains a central concern in epidemiological, dietary, and therapeutic contexts. The gross preponderance of omega-6 fatty acids in the typical American diet, especially through corn oil, is universally considered problematic in terms of physiological stress, particularly inflammatory thresholds, and as an impediment against the beneficial activities of fish oil and other omega-3 fatty acids.[93] Reducing the excess intake of omega-6 oils and shifting the balance of intake toward omega-3 oils can be beneficial in preventing or treating numerous pathological processes. For example, increasing omega-3 sources and reducing omega-6 intake may benefit several cardiovascular risk parameters.[110] Likewise, animal research indicates that increasing omega-3 fatty acid levels and decreasing omega-6 levels could reduce the risk of prostate cancer through beneficial effects on prostate cell membrane composition, cyclooxygenase-2 (COX-2) activity, and lowering of prostaglandin E_2 (PGE_2) production.[111] The Mediterranean diet in particular has become the center of population studies on a broad level and more focused research in terms of particular constituents. In addition to its general emphasis on healthy dietary fats and a significantly higher proportion of omega-3 (vs. omega-6) fatty acids, this dietary approach is rooted in the regional ecosystem and provides a generous supply of whole grains, fresh fruits and vegetables, olive oil (rich in omega-9 fats, which are neutral in the omega-6/omega-3 equation), garlic, and other herbs, with high amounts of protein from fish and seafood and moderate amounts from meat.[112]

Overall, the body of evidence from scientific literature and clinical practice demonstrates the recurring need for a personalized, evolving, comprehensive therapeutic intervention, multidisciplinary in content and integrative in approach, toward the many areas of human physiology and health, as well as pathophysiology and disease that are affected by omega-3 fatty acids. Whether neurological health and cognitive function; inflammatory modulation, free-radical quenching, and immune function; or cardiovascular health and heart disease or stroke, this nutrient class exhibits a diverse range of direct effects and possibilities for therapeutic synergy.

The issue of toxic pollution attributable to humans, particularly methylmercury, dioxins, and PCBs, appears to be the most significant risk and limiting factor associated with dietary intake of omega-3 fatty acids from fish or fish-derived nutraceutical forms. Given the compromised state of oceanic ecologies and systemic damage to sealife, especially fisheries, a global policy of high dietary fish consumption seems unwise and unsustainable, and ultimately may prove irresponsible. Thus, the need arises for increased production and easier access to omega-3 fatty acids from nonfish sources. Shifting to nutraceutical forms of omega-3 intake leads to questions that rarely appear in looking at dietary sources, except among those small populations who consume fish or other sealife sources at high levels, sometimes referred to as "Eskimo" levels. A large and diverse set of well-designed, adequately powered, and long-duration clinical trials will be necessary to answer many of the lingering questions that have arisen from epidemiological and population studies, clinical interventions, and emergent integrative strategies.

This review has considered flaxseed and related plant sources of omega-3 fatty acids, particularly ALA, only in relation to those effects and interactions associated with the fatty acid constituents. Potential preventive, therapeutic, and interactions issues related to the fiber or lignan components, such as proposed laxative or anticancer properties, have not been considered.

In relation to possible interactions involving flaxseed, reasonable application of known pharmacological principles suggests that oral consumption of flaxseed (but not flaxseed oil) may impair absorption of drugs or other nutrients ingested at the same time. Such possible pharmacokinetic effects on bioavailability may be minimized by separating intake by 1 to 2 hours before or 2 to 4 hours after flaxseed ingestion, depending on dose and other variables.

NUTRIENT-DRUG INTERACTIONS

Angiotensin-Converting Enzyme (ACE) Inhibitors

Benazepril (Lotensin), captopril (Capoten), enalapril (Vasotec), enalapril combination drug: enalapril and felodipine

(Lexxel); fosinopril (Monopril), lisinopril (Prinivil, Zestril), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), ramipril (Altace), trandolapril (Mavik).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Note: Specifically in management of IgA nephropathic renal failure.

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Although immunoglobulin A (IgA) nephropathy is the most common primary glomerulonephritis worldwide, the pathophysiology involved is incompletely understood. Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) appear to alter renal hemodynamics and inflammation by acting as substrates for cyclooxygenase (COX) and lipoxygenase (LOX) pathways and shifting the balance toward less potent inflammatory mediators than those produced through arachidonic acid (AA), the primary omega-6 substrate. Omega-3 fatty acids also can modulate inflammatory and immunological responses through eicosanoid-independent mechanisms, including interference with a number of effector pathways triggered by mesangial immune-complex deposition.[114,115] Overall, many of the effects of fish oils in renal disease appear to parallel those observed in preventing the development and progression of cardiovascular disease. Consequently, fish oil may decrease immunological renal injury in patients with IgA nephropathy and thereby slow the decline in renal function.

Coadministration of ACE inhibitor drugs to manage hypertension through angiotensin-converting enzyme (ACE) inhibition may further reduce the rate of renal progression caused by IgA nephropathy, at least in part, by reducing deleterious effects of hypertension.

Research

Fish oil may be beneficial in the treatment of individuals with IgA nephropathy, but findings have been mixed. Donadio, Bergstralh, Spencer, and colleagues in the Mayo Nephrology Collaborative Group have conducted a series of studies into the therapeutic effects of fish oil in treatment of 106 patients with IgA nephropathy. In a 2-year, multicenter, placebo-controlled, randomized trial, Donadio et al.[116] compared the efficacy of fish oil (12 g/day) with that of olive oil (as placebo) in patients with IgA nephropathy who had persistent proteinuria. They observed that 6% of subjects in the fish oil group and 33% in the placebo group exhibited increases of 50% or more in their serum creatinine concentrations during treatment, and that the annual median changes in these concentrations were 0.03 mg/dL (2.7 mmol/L) in the fish oil group and 0.14 mg/dL (12.4 mmol/L) in the placebo group. The authors noted that none of the subjects receiving fish oil discontinued treatment as a result of adverse effects. Ultimately, the cumulative percentage of patients who died or had end-stage renal disease was forty percent in the placebo group after four years and ten percent in the fish-oil group. The authors concluded that in "patients with IgA nephropathy, treatment with fish oil for two years retards the rate at which renal function is lost."[116] Subsequently, Donadio et al.[117] examined the long-term influence of fish oil treatment on renal progression, as indicated by serial serum creatinine and 24-hour urine protein measurements, in this same cohort of 106 patients extending beyond the initial 2-year trial period. Using an increase of 50% or more in the serum creatinine as the primary endpoint and end-stage renal disease (ESRD) as the secondary endpoint, they reported that after a mean follow-up of 6.4 years, 17 patients in the fish oil group versus 29 in the placebo group reached the primary endpoint, and a total of 27 patients (8 in fish oil group vs. 19 in placebo group) developed ESRD. Notably, from an interactions perspective, blood pressure was controlled in all trial subjects through concomitant treatment with ACE inhibitors. Thus, with this long-term study, the authors concluded that "early and prolonged treatment with fish oil slows renal progression for high-risk patients with IgA nephropathy."[117]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating patients with renal disease, specifically IgA nephropathy, are advised to consider administration of fish oil, in conjunction with ACE inhibitors, as a means of reducing renal damage and slowing disease progression. The 12-g/day doses used in some of the relevant research are much higher than typically used in other nononcological therapeutic contexts. However, patients with IgA nephropathy will inherently be closely supervised and regularly monitored. Further research with well-designed and adequately powered clinical trials appears warranted to confirm these consistent but preliminary findings.

Anticonvulsant Medications

Carbamazepine (Carbatrol, Tegretol), clonazepam (Klonopin), clorazepate (Tranxene), divalproex semisodium, divalproex sodium (Depakote), ethosuximide (Zarontin), ethotoin (Peganone), felbamate (Felbatol), fosphenytoin (Cerebyx, Mesantoin), levetiracetam (Keppra), mephenytoin, mephobarbital (Mebaral), methsuximide (Celontin), oxcarbazepine (GP 47680, oxycarbamazepine; Trileptal), phenobarbital (phenobarbitone; Luminal, Solfoton), phenytoin (diphenylhydantoin; Dilantin, Phenytek), piracetam (Nootropyl), primidone (Mysoline), sodium valproate (Depacon), topiramate (Topamax), trimethadione (Tridione), valproate semisodium, valproic acid (Depakene, Depakene Syrup), vigabatrin (Sabril), zonisamide (Zonegran).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **4. Plausible** or **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Long-chain omega-3 fatty acids "increase seizure thresholds, and lower inflammatory mediators, which are increased in patients with epilepsy" and thus "may be useful in the nonpharmacological treatment of patients with epilepsy."[118] Inflammatory mediators appear to play a major role in the pathophysiology of epilepsy, and omega-3 fatty acids can lower plasma inflammatory markers.[119,122] Omega-6 fatty acids, particularly AA, can inhibit sodium currents and synaptic transmission.[123] In contrast, omega-3 fatty acids not only shift the balance away from AA but exert anticonvulsant effects through their activity as anti-inflammatory mediators. Further, EPA reduces proinflammatory mediators by inhibiting phospholipase A_2 (PLA_2)] and COX-2 enzymes

and is itself metabolized to form anti-inflammatory prostaglandins.[118,124,125]

Anticonvulsant medications, such as valproic acid and carbamazepine, may work in part by selectively inhibiting incorporation and turnover of AA, but not DHA, in brain cells.[126,127]

Research

In a very small, open clinical observation, Schlanger et al.[128] reported that a diet enriched with omega-3 fatty acids alleviates convulsion symptoms in patients with chronic epilepsy. In a 12-week, randomized, placebo-controlled, parallel group trial, Yuen et al.[118] investigated the effects of omega-3 fatty acid administration, using 1000 mg of encapsulated fish oil (with 171 mg EPA and 112 mg DHA, and <100 IU vitamin A and <40 IU vitamin D) three times daily, in 57 patients with refractory epilepsy and ongoing treatment with conventional antiepileptic drugs (AEDs). The authors observed a significant reduction in seizure frequency over the first 6 weeks of treatment in the omega-3 group, "but this effect was not sustained." The treatment group also exhibited "a significant increase in EPA and DHA concentrations and a reciprocal fall in arachidonic and linoleic acid concentrations." Notably, "no change in serum AED concentrations was detected." The authors suggested that "further studies are required to examine different omega-3 FA preparations, different doses, longer treatment duration, and larger sample sizes."[118]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Fish oil, as a rich source of EPA and DHA, is known to exert numerous beneficial effects on healthy nervous system and immune function, both nourishing these tissues and reducing inflammatory processes. Physicians treating patient with seizure disorders using anticonvulsant medications are advised to consider coadministration of omega-3 fatty acids. Although evidence reporting reduced frequency of seizures with low dosages is only preliminary, it does indicate that such nutrient support does not adversely affect drug levels. Further clinical trials are warranted to determine safety and efficacy of such synergistic interventions and establish efficacious parameters of dose, patient characteristics, and other influential factors.

Chemotherapy (Cytotoxic Agents)

Including: Bleomycin (Blenoxane), carboplatin (Paraplatin), cisplatin (*cis*-diaminedichloroplatinum, CDDP; Platinol, Platinol-AQ), cyclophosphamide (Cytoxan, Neosar), daunorubicin (Cerubidine), docetaxel (Taxotere), doxorubicin (Adriamycin, Rubex), etoposide (Eposin, Etophos, VePesid, VP-16), fluorouracil (5-FU; Adrucil, Efudex, Efudix, Fluoroplex), gemcitabine (Gemzar), irinotecan (camptothecin-11, CPT-11; Campto, Camptosar), methotrexate (Folex, Maxtrex, Rheumatrex), paclitaxel (Paxene, Taxol), pliamycin (Mithracin), tumor necrosis factor alpha (TNF-α), vinblastine (Alkaban-AQ, Velban, Velsar), vincristine (Leurocristine, Oncorvin, Vincasar PFS).

Effect and Mechanism of Action

Cancer cachexia is "characterized by a lack of a normal anabolic response to the provision of apparently adequate nutrition" and "appears to result from a persistent response to illness stimulated by the cancer resulting in a proinflammatory cytokine and catabolic hormonal environment."[129] These phenomena, along with loss of appetite, adversely affect quality of life and survival in many patients.

Fish oil provides both a nutrient and an anti-inflammatory agent that may enhance benefits of concomitant nutritional intake and may reverse weight loss, with apparent gains in lean tissue and performance status, as well as facilitate normalization of the metabolic environment in patients with some forms of cancer.[130] Coadministration of fish oil during conventional oncology care may reduce loss of appetite and slow the rate of weight loss associated with many forms of chemotherapy, as well as cancer progression, and stabilize adipose tissue, muscle mass, and skeletal integrity.[129,131-135]

Essential fatty acids (EFAs) such as EPA and DHA can alter proinflammatory cytokine production and acute-phase protein synthesis. Fatty acids, especially those derived from fish oil, can alter the activity of cell membrane–bound enzymes (e.g., Na^+,K^+-ATPase, 5′-nucleotidase), levels of various antioxidants, p53 expression, and the concentrations of protein kinase C, and thereby may reduce inflammation and oxidative damage, mitigate tumor cell drug resistance, limit metastasis, and exert direct cytotoxic activity against a variety of tumor cells.[136-138] The effects of fish oil on cardiac function, including supporting normal heart rate variability, suggest that coadministration may also be protective in oncology care, particularly when specific agents or general poor health portend potential damage.[110,139-141]

Research

Fish oil consumption may reduce risk of oncogenesis in some cancer types, particularly breast, colon, renal cell, or prostate cancer.[142-156] However, greater intake of fish does not necessarily enhance survival rates (e.g., from breast cancer).[157]

Administration of fish oil to oncology patients may act in several beneficial ways. With nutrient support the patients may experience reduced severity of wasting common to the pathological processes. Furthermore, the use of these EFAs may reduce adverse effects associated with conventional cancer therapy or provide direct and indirect therapeutic activity against neoplastic diseases. Other agents with anti-inflammatory activity, such as nonsteroidal anti-inflammatory drugs (NSAIDs), or antioxidant activity might also be combined to achieve synergistic effects.

Progressive weight loss and reduced appetite are common features of many types of cancer and contribute not only to a poor quality of life and reduced response to chemotherapy, but also to a shorter survival time than patients with comparable tumors without anorexia and cachexia. Numerous surveys have found that oncology patients are among the patients with the highest rates of self-prescribing nutrients and herbs, with omega-3 fatty acids among the substances most often used.[150] Prevention or treatment of chemotherapy-induced cachexia may be the main reason why fish oil is used within integrative oncology regimens.

Das et al.[158] reported that EPA and gamma-linolenic acid (GLA) "can potentiate the cytotoxicity of vincristine, cisplatinum and doxorubicin on human cervical carcinoma (HeLa) cells *in vitro*. Alpha-linolenic acid (ALA), GLA, EPA, and docosahexaenoic acid (DHA) enhanced the uptake of vincristine by HeLa cells. In addition, DHA, EPA, GLA, and

DGLA [dihomogamma-linolenic acid, the direct precursor to prostaglandin E_1] were found to be cytotoxic to both vincristine-sensitive (KB-3-1) and -resistant (KB-ChR-8-5) human cervical carcinoma cells *in vitro*." Furthermore, "pre-incubation of vincristine-resistant cells with sub-optimal doses of fatty acids enhanced the cytotoxic action of vincristine." Overall, these fatty acids "enhanced the uptake and inhibited the efflux of vincristine and thus, augmented the intracellular concentration" of the antineoplastic agents.

In a series of investigations, Barber et al.[132] studied the efficacy of a fish oil–enriched nutritional preparation in attenuating the progression of the acute-phase protein (APP) response in weight-losing patients with advanced pancreatic cancer, a process believed to shorten survival in such patients. Using a sequential series design, they administered 2 g EPA and 1 g DHA daily to 18 patients with pancreatic cancer for 3 weeks to determine the effects of a fish oil–enriched nutritional formulation on the concentrations of a range of individual APPs; 18 other subjects received full supportive care alone, and six healthy subjects served as additional controls. "At baseline, albumin, transferrin and pre-albumin were significantly reduced and fibrinogen, haptoglobin, alpha-1-acid glycoprotein, alpha-1-antitrypsin, ceruloplasmin and C-reactive protein (CRP) were significantly elevated in the cancer patients compared with healthy controls, reflecting their roles as negative and positive acute phase proteins, respectively." Over the 4-week study period the only significant change in APP concentrations in the treated cancer group was an increase in transferrin. In contrast, there were further significant reductions in albumin, transferrin, and prealbumin and a significant increase in CRP concentration in the control cancer group. The authors stated that these findings "suggest that many positive and negative APP are altered in advanced pancreatic cancer" and that the APP response "tends to progress in untreated patients but may be stabilized by the administration" of a fish oil–enriched nutritional formulation in such a way as to reduce wasting.[132] In a related study, these researchers found that an "EPA-enriched supplement may reverse cachexia in advanced pancreatic cancer."[158]

Integration of fish oils into a comprehensive approach to oncology care may also help prevent or reduce the severity of other degenerative processes, such as decreased bone mineral density and drug-induced cardiac damage, common in this patient population. Scientific knowledge of the potential benefits of fish oils on cardiovascular health in general suggest that they may be beneficial in patients being treated with chemotherapeutic agents known for causing damage to cardiac tissue. In this situation the anti-inflammatory and antioxidant effects of fish oils are among the probable mechanisms of action and the typical response of increased heart rate variability among the desired results. Similarly, the ratio of omega-3 to omega-6 fatty acids appears to play a role in bone health, with higher omega-3 levels contributing to maintaining skeletal integrity during aging or other degenerative processes.[135] Direct evidence of these protective effects in patients with cancer is lacking, but reasonable inferences from broader or related research suggests that further study of these potential synergies is warranted.

In a phase II study involving the combination of "antioxidants, both in the diet and supplemented, pharmaconutritional support, progestagen, and anti-cyclooxygenase-2," Mantovani et al.[159] demonstrated "efficacy and safety" in 44 patients with "cancer-related anorexia/cachexia and oxidative stress." They evaluated data on four variables (clinical, nutritional, laboratory, quality of life) in 39 patients who completed 4 months of an integrative treatment regimen consisting of "diet with high polyphenols content (400 mg), antioxidant treatment (300 mg/d alpha-lipoic acid + 2.7 g/d carbocysteine lysine salt + 400 mg/d vitamin E + 30,000 IU/d vitamin A + 500 mg/d vitamin C), and pharmaconutritional support enriched with 2 cans per day (n-3)-PUFA (eicosapentaenoic acid and docosahexaenoic acid), 500 mg/d medroxyprogesterone acetate, and 200 mg/d selective cyclooxygenase-2 inhibitor celecoxib." They reported significant increases from baseline of body weight, lean body mass (LBM), and appetite; "important decrease of proinflammatory cytokines interleukin-6 (IL-6) and tumor necrosis factor-alpha, and a negative relationship worthy of note was only found between LBM and IL-6 changes," and "a marked improvement" in quality of life as assessed using several standard scoring systems. Of the 39 patients, 22 were determined to be "responders" or "high responders" at the end of the study. Based on these findings, the authors concluded that "the treatment was effective and more importantly was shown to be safe" and that "therefore, a randomized phase III study is warranted."[159]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating patients with cancer who are exhibiting wasting or may be at increased risk of such complications are advised to develop a comprehensive nutritional support program within which fish oil may play a central role. Although the available evidence is largely preliminary or emerging in character, and not wholly characterized by favorable responses, there is little substantial data suggesting any adverse effects from coadministration of fish oils.

Cyclosporine

Cyclosporine (Ciclosporin, cyclosporin A, CsA; Neoral, Sandimmune, SangCya).

◉ **Emerging**

Effect and Mechanism of Action

Cyclosporine is an immunosuppressant agent often administered on a chronic basis after organ transplant and associated with a wide range of often-severe complications, particularly drug-induced nephrotoxicity, which manifests as dose-dependent acute azotemia and chronic (and typically irreversible) progressive renal disease. Thus, cyclosporine induces vasoconstriction and hypertension, as well as other adverse effects. Furthermore, atherosclerosis associated with hyperlipidemia and hypertension is a major cause of morbidity and mortality after renal transplant, and cardiovascular complications are responsible for about 40% of deaths in renal transplant recipients.

Coadministration of omega-3 oils appears to work by several mechanisms, including altering the prostaglandin profile, competitively reducing thromboxane A_2 (TXA_2) synthesis, shifting serum lipid concentrations, exerting vasodilatory effects on afferent arterioles in the glomeruli, decreasing systemic vascular resistance (SVR), and protecting against oxidative damage.[160-162] The combination of omega-3 fatty acids with cyclosporine may show promise against nephrotoxicity

and hypertension in transplant patients, especially as prophylaxis.

Research

Findings from numerous clinical trials investigating coadministration of fish oil with cyclosporine after cardiac, liver, and renal transplant demonstrate improved renal function (i.e., glomerular filtration rate [GFR] and serum creatinine) and reduced incidence of hypertension compared with patients not treated with concomitant fish oil.[163-165] Nevertheless, other studies report more limited benefit regarding kidney function. Overall, circulating drug levels, rates of rejection, and graft survival have not been adversely affected.

Omega-3 polyunsaturated fatty acids (PUFAs) are generally recognized as beneficial for individuals with chronic renal insufficiency, but studies have shown some important differences between initial and longer-term responses and between responses in rejectors versus nonrejectors. In an early study with 14 subjects, Sweny et al.[160] reported that coadministration of fish oil preserves residual renal function in renal transplant recipients with chronic vascular rejection. Also in 1989, Stoof et al.[166] published the findings from a small preliminary study that found adding 6 g/day of fish oil "can reduce CyA-associated renal dysfunction in psoriasis patients."

Subsequently, Homan van der Heide, Bilo, and a team of Dutch researchers conducted a lengthy series of studies focusing on use of fish oil in allograft patients. In a double-blind, placebo-controlled, prospective, randomized clinical trial, these investigators followed the course of early postoperative rejection episodes in 21 stable cyclosporine-treated renal transplant recipients. They found that renal transplant recipients benefited from omega-3 fatty acids (6 g daily providing 30% EPA and 23% DHA) during cyclosporine therapy, versus placebo using corn oil (50% omega-6). After 3 months, blood pressure decreased in the omega-3 group, and GFR and renal blood flow increased by 20.3% and 16.4%, respectively. The authors concluded that their results showed that fish oil coadminstration "has considerable effects on renal function and blood pressure in stable CsA-treated renal transplant recipients."[167] In a later randomized prospective trial, they compared the effects of 1-month coconut oil (6 g daily) with 6 g daily fish oil (providing 30% EPA and 20% DHA as their methyl esters) on the incidence and course of early postoperative rejection in 88 first cadaveric, cyclosporine-treated renal transplant recipients. They reported that, while prerejection renal function and the decline of renal function during the rejection episode were similar before treatment, "the rejecting and fish oil-treated patients showed a significant better recovery of renal function after a histologically confirmed rejection episode," with creatinine clearance being 43 mL/min/1.73 m^2 in the fish oil + rejection group versus 27 mL/min/1.73 m^2 in the coconut oil + rejection group, and serum creatinine being 183 and 283 mmol/L, respectively. Notably, "nonrejecting fish oil-treated patients showed no better renal function than the nonrejecting coconut oil-treated patients," although "cyclosporine trough levels were significantly higher in the fish oil-treated group." However, even though fish oil favorably influenced renal function in the initial recovery phase after a rejection episode in cyclosporine-treated renal transplant recipients, the authors concluded that 1 month after grafting there is no difference in the incidence of rejection episodes, renal function in the absence of rejection, and decline in renal function during a rejection episode between the fish oil– and coconut oil–treated patients.[168]

Fish oil can prevent or reduce cyclosporine-induced nephrotoxicity and limit decline in glomerular filtration rate in allograft patients.[169] In 1991, Brouwer et al.[170] observed that fish oil (3 g daily for initial 6 weeks, then 6 g/day) ameliorates established cyclosporin A nephrotoxicity after heart transplantation. Badalamenti et al.[171] conducted a placebo-controlled, prospective, double-blind, randomized study to evaluate the renal effects of 12 g daily omega-3 fatty acids (vs. corn oil) on cyclosporine-induced nephrotoxicity in 26 liver transplant recipients. After 2 months, subjects in the fish oil group demonstrated a 22% increase in effective renal plasma flow, 33% increase in GFR, 17% increase in renal blood flow, and 20% decreased in calculated total renal vascular resistance; these parameters in the corn oil group were unchanged.

Following studies showing benefits of initiating fish oil at the time of engraftment, Bennett et al.[172] conducted a double-blind, placebo-controlled trial investigating the implications of the initial versus 16-week delay in the introduction of fish oil after allograft surgery. They reported that all observed occurrences of "acute CsA [cyclosporin A] nephrotoxicity occurred in placebo-treated patients without differences in whole blood CsA among toxic patients, other placebo patients, and EPA-treated recipients." Notably, diastolic blood pressure fell by 9 mm Hg during the second treatment period in subjects receiving 18 g EPA and by 10 mm Hg in those receiving 9 g EPA, but rose by 2 mm Hg in placebo patients receiving corn oil. Nevertheless, with delayed introduction, "there were no differences in glomerular filtration rate, renal blood flow, or creatinine clearance among groups" at the end of the study. Thus, these authors concluded that based "on our experience and that in the literature, administration of omega-3 fatty acids for purposes of kidney protection would seem to be most useful when started early after surgery," and that delayed administration was "associated with minor clinical benefits."[172]

The coadministration of fish oil may prevent or reduce hypertension in transplant patients treated with cyclosporine. Since the late 1980s, the effects of omega-3 fatty acids on hypertension after transplantation have been widely recorded, with positive positive in a majority of human studies. Most, but not all, clinical trials have shown that in allograft patients treated with cyclosporine immunosuppressant therapy, addition of 4 to 6 g daily of omega-3 fatty acids from fish oil can reduce hypertension, compared with placebo.[161,166,173,174]

Ventura et al.[161] conducted a randomized double-blind trial with 20 orthotopic cardiac transplant recipients showing that administration of fish oil may reverse changes in the prostaglandin profile and thereby counteract cyclosporine-induced hypertension related to vasoconstriction of the afferent arterioles in the glomeruli. Compared with omega-6 fatty acids (placebo group), subjects treated with omega-3 fatty acids (3 g/day) "demonstrated a significant reduction in mean arterial pressure (120 +/– 7 versus 102 +/– 7 mm Hg; P = .0001) associated with a decrease in systemic vascular resistance." Thus, the authors reported that omega-3 fatty acids appear to induce a "beneficial change in the prostaglandin profile" that provides a "vasodilatory effect" and thereby reduces "blood pressure by decreasing systemic vascular resistance." They concluded that "therefore, [fish oil] can be used as an adjuvant for the treatment of hypertension in cyclosporine-treated cardiac transplant recipients."[161]

In a subsequent randomized trial, Andreassen et al.[175] found that postoperative daily administration of 4 g/day omega-3 fatty acids in heart transplant recipients is "effective as hypertension prophylaxis, depending on increases in serum eicosapentaenoic and docosahexaenoic

acids," compared with an equal dose of corn oil as placebo. These patients were being treated with an immunosuppressive regimen consisting of cyclosporine (6 mg/kg body weight), azathioprine (2 mg/kg/day), and prednisolone (0.2 mg/kg/day), as well as alpha-tocopherol (3.7 mg), beginning 4 days postoperatively and continuing for 6 months. Systolic blood pressure decreased in the omega-3 group and increased in the control group after 6 months. Although diastolic blood pressure increased in both groups, this increase was statistically significant in the control group. The authors noted that the "decrease in systolic blood pressure was inversely proportional to increases in concentrations of serum eicosapentaenoic and docosahexaenoic acid." Also, although after 6 months "the endothelial-dependent phase of the reactive hyperemic response remained unchanged in the treatment group, it decreased significantly in the placebo group." The authors suggested that "preservation of microvascular endothelial function . . . may contribute to the hypotensive role of omega-3 fatty acids."[175]

Holm et al.[176] found that omega-3 fatty acids improve blood pressure control and preserve renal function in hypertensive heart transplant recipients years after transplantation. In a double-blind trial, they studied 45 clinically stable hypertensive heart transplant recipients 1 to 12 years after transplantation who were randomized to receive either 3.4 g omega-3 fatty acids daily or placebo for 1 year. Although subjects in the placebo group demonstrated a nonsignificant increase in diastolic blood pressure of 3 ± 2 mm Hg and a 14% increase in SVR, those in the fish oil group exhibited "no change in blood pressure or systemic vascular resistance."[176] Interestingly, in a related study, these researchers also found that omega-3 fatty acids enhance tumor necrosis factor-alpha (TNF-α) levels in heart transplant recipients.[177]

Although most studies report clear benefits that include improved kidney function, not all studies have found long-term improvements with fish oil; evidence of renal benefits is lacking in findings from several trials beyond that previously discussed.[168,172] Hansen et al.[178] found no effect of dietary fish oil on renal hemodynamics, tubular function, or renal functional reserve in long-term renal transplant recipients in a 10-week study involving nine healthy volunteers and two groups (nine subjects each) of stable, long-term kidney-transplanted patients treated with maintenance low-dose CsA or without CsA. The authors concluded that "long-term renal transplant recipients treated with a low maintenance dose of CsA had a well-preserved renal functional reserve," and that concomitant "fish oil in these patients did not improve renal function." Similarly, in a randomized, placebo-controlled, double-blind trial, Kooijmans-Coutinho et al.[179] reported "no beneficial effect after renal transplantation" after comparing data from two groups of 25 recipients of primary cadaveric renal allografts who had been treated with CsA and 6 g/day fish oil or coconut oil for 3 months. One year after transplantation, they found no significant differences between the fish oil–treated group and the control patients regarding renal function, blood pressure and antihypertensive drug use, number of rejection episodes, and renal histopathological and immunohistochemical studies. Such conclusions, however, were qualified with reference to the dose of fish oil used and the limited time of treatment.

In a randomized clinical trial involving 30 patients who had received a first cadaveric renal transplant with delayed graft function, Santos et al.[162] administered 6 g fish oil daily, containing 30% EPA and 20% DHA, with 1 U vitamin E and 5 U vitamin A per gram, or placebo, beginning 2 days postoperatively, for 12 months. Notably, beta-blocking agents, in combination with a diuretic or a centrally acting vasodilatory agent, were administered for hypertension, with calcium channel blockers and ACE inhibitors used only as a second-line treatment. The authors noted that "patients in the fish oil group required significantly less antihypertensive therapy to maintain similar blood pressure values." However, fish oil coadministration "did not have any beneficial effect on renal function, incidence of acute rejection episodes, or 1-year graft survival." Noting the contrast in these findings with those of other trials (except the one just discussed[179]), the authors qualified their conclusions by adding that renal "function as measured by GFR and creatinine clearance was consistently slightly better in the fish oil group, and it is possible that the power of the study was insufficient to detect a beneficial effect."[162]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating organ allograft transplant patients with cyclosporine or other nephrotoxic immunosuppressant drugs are advised to consider coadministration of fish oil, particularly in patients exhibiting hypertension or renal damage. Prophylaxis against cyclosporin A nephrotoxicity may also be indicated. The amount of omega-3 oils used to elicit a beneficial response in hypertension has varied. Researchers have started with initial doses of 3 g daily for 6 weeks, followed by 6 g daily for up to 1 year; doses as high as 12 g daily have been used in research contexts. Inherently, initial treatment of allograft patients after transplant surgery requires direct supervision and close monitoring, and long-term care involves chronic immunosuppressant therapy with regular monitoring of blood pressure, kidney function, and drug levels. The available data suggest compatibility of such concomitant fish oil use with standard hypertensive medications, such as beta blockers or ACE inhibitors, but any polypharmaceutical intervention warrants individualized adjustments crafted to the needs and vulnerabilities of the given patient.

Etretinate

Evidence: Etretinate (Tegison).
Similar properties but evidence lacking for extrapolation: Acitretin (Soriatane).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Etretinate is an oral retinoid used in the treatment of recalcitrant psoriasis vulgaris. Omega-3 fatty acids are known for their anti-inflammatory activity, as well as their role in the integrity of cell membranes, and may have independent therapeutic value in the treatment of patients with inflammatory dermatological conditions. The combination of these agents may provide an additive or synergistic effect.

Research

In two small clinical trials, Danno et al.[180,181] first found that combining low-dose etretinate and EPA proved effective treatment for psoriasis. They concluded that "better and more rapid improvement was obtained with the combination therapy for 12 weeks than with low-dose etretinate monotherapy" and

noted that EPA "was safe, and adverse reactions due to low-dose etretinate were mild or tolerable." Notably, however, in the earlier study,[180] they found that, along with the etretinate combination therapies, CsA monotherapy also demonstrated "greater inhibitory effects on the endothelial expression of the adhesion molecules than the other monotherapies" tested.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing oral etretinate for patients with recalcitrant psoriasis are advised to consider coadministration of fish oil for its probable value in enhancing the therapeutic efficacy of the intervention. However, etretinate is no longer commercially available in the United States and Canada. Etretinate has not been marketed in the U.S. for years because it remains in the body (stored in fatty tissue) for a very long time, with attendant teratogenic risk in females of childbearing age. In the U.S. it has been replaced by acitretin, which remains in the system for months rather than years; discontinuation of acitretin for 3 years before pregnancy is recommended, but no period of discontinuation before pregnancy may be safe for etretinate. Drinking alcohol, however, can convert acitretin into etretinate, which then persists in body fat for many years, perhaps decades. Further research with well-designed, adequately powered clinical trials is warranted to study the possible synergistic activity between fish oil omega-3 fatty acids and acitretin (soriatane), which is closely related to etretinate chemically, and likely functions via a similar mechanism of action.

It is also critical to warn all female patients of childbearing age of the potential teratogenic effects inherent to etretinate, acitretin, or other oral retinoids. Principles of conservative practice are moving toward a general contraindication of retinoids in female patients who could become pregnant. Fish oil, in contrast, may provide multiple benefits to pregnant or potentially pregnant women in terms of fetal development.

HMG-CoA Reductase Inhibitors (Statins)

Atorvastatin (Lipitor), fluvastatin (Lescol, Lescol XL), lovastatin (Altocor, Altoprev, Mevacor); combination drug: lovastatin and niacin (Advicor); pravastatin (Pravachol), rosuvastatin (Crestor), simvastatin (Zocor); combination drug: simvastatin and extended-release nicotinic acid (Niaspan).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:
2. Probable

Evidence Base:
◉ **Emerging,** possibly
● **Consensus**

Effect and Mechanism of Action

Epidemiological and clinical evidence demonstrates that fish oil can lower plasma lipid levels, especially triglycerides. However, omega-3 fatty acids may cause small elevations in low-density lipoprotein (LDL) concentrations, with more substantial elevations in individuals with familial combined hyperlipidemia, but with a paradoxical lowering of LDLs at high doses (e.g., 32 g/day).[55,155] The mechanisms underlying the protective action of omega-3 PUFAs against coronary artery disease (CAD) remain to be established. However, their multiple cardiovascular effects appear to derive from numerous potential mechanisms, including lower levels of serum lipids, antithrombotic properties and relaxation in coronary arteries, enhanced arterial wall pliability, anti-inflammatory properties, reduced oxidative damage, antiplatelet-derived growth factor properties, natural ligands for peroxisome proliferator-activated receptors (PPARs), and antiarrhythmic properties.[182-197]

Statin drugs reduce serum total cholesterol concentrations and the risk of CAD in individuals with hypercholesterolemia by interfering with the activity of the hepatic enzyme hydroxymethylglutaryl–coenzyme A (HMG-CoA) reductase. These drugs alone, however, are usually not effective in reducing serum triglyceride concentrations, and they are known for dose-related adverse effects.

The concomitant administration of omega-3 fatty acids, through dietary or nutraceutical sources, during statin therapy could theoretically impair the LDL-lowering activity of agents in this drug class. However, coadministration may also have a cumulative therapeutic benefit for individuals with combined hyperlipidemia through complementary effects within a comprehensive lipid management strategy.

Research

Over the past 20 years or more, a broad range of clinical trials have usually, but not always, found that fish oil can reduce triglyceride levels by 25% to 44%.[56,57,198-203] Research indicates that dietary fish, fish oil, or EPA or DHA alone may further elevate high-density lipoprotein (HDL) cholesterol, reduce risk factors associated with atherothrombotic diseases (particularly CAD), and improve other aspects of lipid profile and cardiovascular health.[41,57,97,203-206] Conversely, numerous trials have reported elevations in LDL concentrations, although such increases may not persist.[57] Overall, when Studer et al.[102] conducted a review of data on the efficacy and safety of different antilipidemic agents and diets on mortality, they found that fish oil and statins were the most effective interventions for lowering cardiac mortality risk, fish oil being superior to statin therapy. The benefits of omega-3 fatty acids for risk reduction have been attributed to several factors, including moderating effects on heart arrhythmias, support of normal heart rate variability, and antithrombotic and anti-inflammatory properties.[102,110,140,141]

Most research shows that the concomitant administration of fish oil and a statin drug can produce a broader and more effective therapeutic effect in the treatment of dyslipidemic individuals, by lowering both cholesterol and triglyceride concentration, than either agent alone. In a preliminary trial, Nakamura et al.[207] confirmed the combined effects of HMG-CoA reductase inhibitors and "eicosapentaenoic acids" on serum lipid profile and plasma fatty acid concentrations in patients with hyperlipidemia. The authors administered 900 or 1800 mg per day of the ethyl ester of EPA to patients with hyperlipidemia who had been treated with HMG-CoA reductase inhibitors for 30 months (±6 months). They reported three significant findings after 3 months of combination therapy. Serum total cholesterol and triglyceride concentrations were significantly decreased (from 5.63 ± 0.23 mmol/L to 5.02 ± 0.20 mmol/L); serum HDL cholesterol concentrations were significantly increased (from 1.23 ± 0.12 mmol/L to 1.34 ± 0.13 mmol/L); and plasma EPA concentrations and the ratio to AA in plasma were also significantly increased (from 101.9 ± 8.1 mg/L to 181.8 ± 23.9 mg/L, and from 0.640 ± 0.075 to 1.211 ± 0.170, respectively). Thus, they concluded that these "results suggested that the combination therapy of HMG-CoA reductase inhibitors and eicosapentaenoic acid was effective for patients with hyperlipidemia."[207]

Clinical trials by Nordoy et al.,[208,209] as well as Contacos et al.[43] and Liu et al.,[206] have demonstrated additive therapeutic effects on hemostatic risk factors, postprandial hyperlipemia, serum lipid profile, plasma fatty acid concentrations, LDL

subfractions, and plasma lipoproteins from coadministration of omega-3 fatty acids with simvastatin, pravastatin, and atorvastatin in patients with combined hyperlipemia. In the Japan EPA Lipid Intervention Study (JELIS), a large, prospective, randomized, open-label, blinded endpoint trial, Yokoyama and Origasa[57] studied the long-term use of highly purified EPA ethyl ester (600 mg three times daily), in conjunction with an HMG-CoA reductase inhibitor (either pravastatin or simvastatin), in preventing cardiovascular events in Japanese patients with hypercholesterolemia over a period lasting up to 5 years. Among their intermediate findings, they found that the combination of EPA and statins is an effective preventive measure against heart disease. They observed that each therapy alone successfully reduced the LDL to the same degree, approximately 26%. Moreover, they reported a 19% reduction risk among patients who experience sudden cardiac death, heart attack, or angina and who undergo coronary artery bypass surgery while treated with this combination therapy, versus statin therapy alone.

Several short-term and small studies, particularly those involving individuals with familial hypercholesterolemia, have produced less consistent findings on various lipid factors and suggested an increased risk of adverse effects, such as elevated LDL concentrations and spontaneous epistaxis, after treatment with variable doses of fish oil.[53,78] Ullmann et al.[210] reported additive effects with the combination of lovastatin and fish oil in patients with familial hypercholesterolemia. Balestrieri, Salvi, et al.[211] conducted a double-blind, placebo-controlled, randomized crossover trial involving 14 subjects affected by familial heterozygous hypercholesterolemia on chronic treatment with simvastatin. They observed that coadministration of fish oil ethyl ester (5.1 g/day) on lipid and lipoprotein serum concentrations did not produce "any significant variation" on total cholesterol, LDL cholesterol, HDL cholesterol, triglycerides, apoprotein B, apoprotein AI, or lipoprotein(a) during a 4-week treatment period. The authors interpreted their findings to "suggest that the possible favourable influence of fish oil on the progression of atherosclerosis in these high-risk patients might involve mechanisms which are different from lipid metabolism." This same group of Italian researchers conducted another small trial in which they administered six capsules of fish oil daily for 4 weeks to 10 patients (mean age, 49 ±14 years) "with heterozygous familial hypercholesterolemia who had high levels of lipoprotein (Lp)(a) (>30 mg/dl) and were receiving chronic treatment with simvastatin." Each 1-g "fish oil capsule contained almost 850 mg of omega-3 fatty acids with a ratio of eicosapentaenoic acid:docosahexaenoic acid of 1:1; the total daily dosage of omega-3 fatty acid was 5.1 gm/day." They reported that "mean serum Lp(a) levels did not change significantly" after 2 and 4 weeks of concomitant fish oil, and triglyceride levels decreased by 23% after 2 weeks (from 1.355 ± 0.38 mmol/L to 1.05 ± 0.35 mmol/L) and by 33% after 4 weeks (to 0.91 ± 0.18 mmol/L). Notably, total cholesterol and LDL cholesterol "showed a less pronounced but still statistically significant reduction of 8% (from 7.33 ± 2.55 mmol/L to 6.76 ± 1.31 mmol/L) and 9% (from 5.52 ± 1.98 mmol/L to 5.00 ± 1.67 mmol/L), respectively," after 2 weeks, followed by a "14% decrease in total cholesterol (to 6.30 ± 1.36 mmol/L) and LDL cholesterol (to 4.75 ± 1.49 mmol/L)" after 4 weeks. They observed a lack of significant change in HDL cholesterol concentrations. They cautioned that their findings of a positive "effect of fish oil on Lp(a) levels must be confirmed by double-blind, placebo-controlled studies before any definite conclusion can be drawn."[212]

In a 1991 review, Simopoulos[55] noted that in "patients with hyperlipidemia, omega 3 fatty acids decrease low-density lipoprotein (LDL) cholesterol if the saturated fatty acid content [of the diet] is decreased, otherwise there is a slight increase, but at high doses (32 g) they lower LDL cholesterol; furthermore, they consistently lower serum triglycerides in normal subjects and in patients with hypertriglyceridemia, whereas the effect on high-density lipoprotein (HDL) varies from no effect to slight increases." Thus, although fish oil therapy may alter LDL levels to varying degree, with the greatest risk being among individuals with familial hypercholesterolemia, such adverse effects are neither universal nor unaccompanied by beneficial effects, and may be strongly influenced by dose and diet.

The beneficial effects of integrative therapy combining omega-3 fatty acids and a statin drug (especially with concomitant aerobic exercise) appears to exert a particular influence among individuals with type 2 diabetes, particularly in controlling lipid levels, without significant risk of impairing glycemic control.[213] Kromhout et al.[213a] demonstrated an inverse relation between fish consumption and 20-year mortality from coronary heart disease (CHD) that may have particular relevance to triglyceride levels in the context of diabetes. Durrington et al.[202] investigated the triglyceride-lowering effectiveness, safety, and tolerability of 2 g daily of a proprietary concentrate of omega-3, long-chain PUFAs (Omacor), derived from fish oil but containing 84% of the total as opposed to an average of 35% in fish oil, over 1 year in 59 patients with established CHD and persisting hypertriglyceridemia (>2.3 mmol/L), despite simvastatin therapy (10-40 mg daily). The authors reported "a sustained significant decrease in serum triglycerides" (20%-30%) and in very-low-density lipoprotein (VLDL) cholesterol (30%-40%) in patients receiving omega-3 concentrate at 3, 6, and 12 months, compared with either baseline or placebo. The authors observed no deleterious effect on LDL or HDL cholesterol or on biochemical and hematological safety tests. Notably, the fish oil was well tolerated in general, and patients with diabetes in particular demonstrated no adverse effect on glycemic control. Overall, the subjects with diabetes exhibited a "decrease in serum triglyceride, which was at least as great as in non-diabetic patients." Thus, the authors concluded that "Omacor was found to be a safe and effective means of lowering serum triglycerides over one year in patients with CHD and combined hyperlipidaemia, whose triglycerides remained elevated despite simvastatin treatment."[202]

In response to preliminary data suggesting that fish oil may impair glycemic control in individuals with non-insulin-dependent diabetes mellitus (NIDDM), Dunstan et al.[72] conducted a controlled, 8-week trial to examine the effects of moderate aerobic exercise and a low-fat diet, including fish, on serum lipids and glycemic control in dyslipidemic NIDDM patients. The investigators randomly assigned 55 "sedentary NIDDM subjects (with serum triglycerides > 1.8 mmol/L and/or HDL cholesterol < 1.0 mmol/L) to a low-fat diet (30% daily energy intake) with or without one fish meal daily (3.6 g omega-3/day) and further randomized to a moderate (55-65% VO_2max) or light (heart rate < 100 bpm) exercise program." They reported that among the 49 subjects who completed the study, "moderate exercise improved aerobic fitness (VO_2max) by 12%," and fish consumption reduced triglycerides (0.80 mmol/L) and HDL_3 cholesterol (0.05 mmol/L) and increased HDL_2 cholesterol. Based on these findings, the authors concluded that a "reduced fat diet incorporating one daily fish meal reduces serum triglycerides and increases HDL_2 cholesterol in dyslipidemic NIDDM patients" and noted that potential

omega-3-induced deterioration in glycemic control "can be prevented by a concomitant program of moderate exercise."[72]

The increased risk of cardiovascular disease in insulin-resistant, obese individuals is considered to result, at least in part, from hepatic accumulation of lipid substrates that perturb apolipoprotein B-100 (apoB) metabolism. In a placebo-controlled trial involving 48 subjects, Chan et al.[214] found that the combination of fish oil (4 g/day) and atorvastatin (40 mg/day) was effective in treating dyslipidemia in obese, insulin-resistant men. The authors demonstrated that atorvastatin significantly decreased plasma apoB-containing lipoproteins by increasing the fractional catabolic rate of VLDL-apoB, intermediate-density lipoprotein (IDL)–apoB, and LDL-apoB. Concurrently, they observed that fish oil significantly decreased plasma triglycerides and VLDL-apoB levels and decreased VLDL-apoB secretion rate; conversion of VLDL to LDL increased. Overall, the combination of atorvastatin and fish oil decreased VLDL-apoB secretion and increased the fractional catabolic rate of apoB in each lipoprotein fraction, compared with placebo, as well as the percent conversion of VLDL to LDL. Notably, none of the interventions altered insulin resistance. The investigators concluded that "atorvastatin increased hepatic clearance of all apoB-containing lipoproteins, whereas fish oils decreased hepatic secretion of [VLDL]-apoB. The differential effects of atorvastatin and fish oils on apoB kinetics support their combined use in correcting defective apoB metabolism in obese, insulin-resistant subjects."[214]

Although known for its anti-inflammatory activity, fish oil alone is not as effective as treatment with atorvastatin alone or a combination of atorvastatin and fish oil in reducing C-reactive protein (CRP) levels in dyslipidemic, obese individuals with visceral obesity and increased plasma high-sensitivity CRP.[215]

Shifting the dietary omega-6 to omega-3 ratio by increasing omega-3 sources and reducing omega-6 sources may also benefit several cardiovascular risk parameters.[110]

In related research, Wander et al.[216] conducted a double-blind crossover trial involving 48 women, equally divided between women using and not using hormone replacement therapy (HRT), to evaluate the effects of RRR-alpha-tocopheryl acetate (alpha-tocopheryl acetate) and HRT on the oxidative susceptibility of LDL in postmenopausal women consuming a 15-g fish oil product daily, versus placebo. They assessed LDL resistance to oxidative modification by calculating lag time, propagation rate, and maximum production of conjugated dienes. They observed that consumption of fish oil and alpha-tocopheryl acetate "increased plasma and LDL alpha-tocopherol contents significantly and lengthened lag time (at even the lowest concentration) but had no significant effect on propagation rate or maximum production compared with values measured after consumption of fish oil alone." Also, fish oil with placebo shortened lag time and slowed propagation rate in women both using and not using HRT. In their central finding, the authors observed that women "not using HRT had faster propagation rates and higher maximum production than women using HRT; after supplementation with fish oil and alpha-tocopheryl acetate these differences prevailed." Consequently, the authors concluded that the combination of fish oil and doses of alpha-tocopheryl acetate "as low as" 100 mg daily "increase the resistance of LDL to oxidation" and that "HRT and fish oil supplements may independently affect LDL oxidative susceptibility."[216]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians treating individuals with combined dyslipidemia, particularly hypercholesterolemia and hypertriglyceridemia, using statin therapy are advised to consider a comprehensive strategy combining pharmacological, nutritional, dietary, and lifestyle components customized to optimize lipid balance and metabolism, maximize patient participation and compliance, and secure a safe, sustainable, and effective intervention aimed at long-term health, prevention, and treatment. Eating a meal based around omega-3-rich fish two to three times a week is generally advisable, tempered only by risks of mercury or other toxic pollutants. In individuals with elevated risk for or diagnosed with cardiovascular disease, 1 to 3 g fish oil, at standard EPA/DHA proportions, in capsules or other nutraceutical forms represents a minimal daily dose, generally not needing professional supervision, whereas 4 to 6 g daily, or use of an equivalent concentrated product, is often indicated, but under the supervision of a health care professional. Continued research is warranted to clarify common and divergent effects of dietary fish, fish oils of standard composition, purified fish oils, and esterified EPA/DHA in both research and clinical settings.

The role of fish oil within such an integrative approach has been well established and can be optimized through coadministration of garlic, niacin (or inositol hexaniacinate), naturally occurring forms of vitamins A, E, and C, magnesium, potassium, and coenzyme Q10. For example, concomitant administration of garlic may provide a synergistic effect in lowering triglycerides while preventing the expected moderate fish oil–induced rise in LDL cholesterol.[58] The importance of regular exercise and a balanced diet rich in these nutrients cannot be overemphasized, and persistent and supportive cultivation of healthful behavioral changes cannot be underestimated.

By inhibiting the mevalonate pathway, the mechanism of action of statin drugs inherently impairs the endogenous synthesis of coenzyme Q10 (coQ10), an essential mitochondrial antioxidant produced through HMG-CoA reductase. Thus, as a protective measure, many health care professionals experienced in nutritional therapies prescribe coQ10 to prevent adverse effects from this action. Evidence is lacking, however, to prove a high incidence of broad-spectrum, clinically significant adverse effects (e.g., heart failure) or to confirm the advantages of concomitant prophylactic coQ10.[217]

Relatively small amounts of fish oil can have beneficial effects on plasma triglyceride levels in many hypertriglyceridemic patients. Importantly, however, doses used in clinical trials were typically 3 to 6 g per day, and the preparations used sometimes had modified proportions of DHA and EPA or were proprietary concentrated products. Further, although the medical literature, especially secondary and derivative material, carries an abundance of warnings that fish oil intake exceeding 3 g/day may increase the risk of bleeding, reports of such adverse effects are rare among the available primary clinical findings and qualified published case reports. If such events were common at a clinically significant level of severity, a sizable body of literature would be expected, not only amid the 30 years of clinical trials, but more broadly, given the widespread use of fish oil among the general public, especially within the population of patients with cardiovascular disease. Clearly, further research into the probability and circumstances of such potential adverse events is warranted given usage patterns and the reasonable pharmacological and physiological underpinning of the cause for concern. Overall, platelet antiaggregation and changes in cell membrane constituents may increase certain risks in some individuals or with certain pathologies; nevertheless, improved viscosity, arterial pliability, antiarrhythmic activity, and other

properties are never mentioned as possible source of adverse reactions.

The potential for elevated LDL cholesterol and apoB levels and increased LDL/HDL cholesterol ratio suggests the need for careful monitoring of plasma lipoprotein changes during fish oil administration, as well as careful evaluation of their long-term benefits.

Selective Serotonin Reuptake Inhibitor (SSRI) Antidepressants

Citalopram (Celexa), escitalopram (S-citalopram; Lexapro), fluoxetine (Prozac, Sarafem), fluvoxamine (Faurin, Luvox), paroxetine (Aropax, Deroxat, Paxil, Seroxat), sertraline (Zoloft).

Similar properties but evidence lacking for extrapolation: Selective serotonin reuptake inhibitor/serotonin-norepinephrine reuptake inhibitor (SSRI/SNRI) antidepressants: Duloxetine (Cymbalta), venlafaxine (Effexor).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

○ **Preliminary**

Effect and Mechanism of Action

Omega-3 fatty acids, particularly DHA, are a major component of neuronal tissue, particularly in the gray matter of the brain, and deficient states are associated with a wide range of neurological and psychological conditions. An epidemiological association has occasionally been proposed between populations with high rates of fish and fish oil consumption and low rates of depressive disorder.[218,219] Normal serotonin synthesis requires the availability of an ample supply of EFAs and as such provides for the intended activity of SSRIs in maintaining elevated levels of circulating serotonin as a primary mechanism of action in treating depression. The administration of omega-3 fatty acids, particularly fish oils, may enhance neurological activity and psychological states and complement or directly interact with SSRI medications in the treatment of individuals with depression, emotional lability, aggression, or other problematic behaviors.

Research

Although research into the effects of omega-3 fatty acids in the treatment of individuals with depression and a range of other mood disorders is rapidly emerging, the direct investigation of the concomitant administration of conventional antidepressants, particularly SSRIs, with therapeutic doses of omega-3 and other EFAs remains limited.

Using a rodent model, Kodas et al.[95] showed an association between chronic alpha-linolenic acid (ALA) deficiencies and decreased levels in overall serotoninergic neurotransmission. The authors reported that "chronic n-3 polyunsaturated fatty acid dietary deficiency induced changes in the synaptic levels of 5-HT both in basal conditions and after pharmacological stimulation with fenfluramine," and that higher "levels of basal 5-HT release and lower levels of 5-HT-stimulated release were found in deficient than in control rats." These neurochemical modifications were reversed once a balanced diet providing adequate EFAs was administered.

In a randomized, double-blind, placebo-controlled trial involving 36 subjects diagnosed with major depression, Marangell et al.[220] failed to show a significant effect of DHA monotherapy (2 g/day), versus placebo, after 6 weeks.

The limited human research directly investigating coadministration of omega-3 fatty acids, DHA, EPA, or fish oil in patients being treated with SSRI antidepressants suggest a probable benefit, but evidence is insufficient to support a broad, well-founded conclusion. In a double-blind, placebo-controlled trial involving 70 subjects with persistent/recalcitrant depression despite conventional therapy, Peet and Horrobin[221] found that coadministration of ethyl-EPA (a modified form of EPA) improved symptoms. Findings from several small, double-blind clinical trials indicate enhanced therapeutic benefits using ethyl-EPA or mixed EFAs.[222-224] In contrast, Silvers et al.[225] failed to observe therapeutic benefit with fish oil as an adjunctive intervention.

Nemets et al.[218] conducted a 4-week, parallel-group, double-blind study involving 20 patients diagnosed with major depressive disorder to study the effects of adding 1 g twice daily of ethyl ester of eicosapentaenoic acid (E-EPA) to maintenance medication treatment for recurrent unipolar depressive disorder of at least 3 months' duration. The authors reported "highly significant benefits" in subjects treated with omega-3 fatty acid compared with placebo by the third week of treatment; for example, 6 of 10 patients "receiving E-EPA but only one of 10 patients receiving placebo achieved a 50% reduction in Hamilton depression score." They further added that it was "not possible to distinguish whether E-EPA augments antidepressant action in the manner of lithium or has independent antidepressant properties of its own."[218]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing SSRI medications are advised to consider coadministration of fish oil as a source of omega-3 fatty acids, especially in depressed patients who rarely or never eat fish or take OTC products containing fish oil. The weight of evidence from the scientific literature suggests that such nutritional support may have independent and additive beneficial effects. Findings indicating that fish oil might impair the therapeutic activity of SSRI antidepressant are unavailable, as are qualified case reports of adverse events. Nevertheless, even with the strong safety profile of fish oil therapy, professional supervision and regular monitoring are warranted.

Sulfasalazine (and Oral Corticosteroids)

Sulfasalazine (salazosulfapyridine, salicylazosulfapyridine, suphasalazine; Apo-Sulfasalazine, Azulfidine, Azulfidine EN-Tabs, PMS-Sulfasalazine, Salazopyrin, Salazopyrin EN-Tabs, SAS).

Interaction Type and Significance

☼ **Prevention or Reduction of Drug Adverse Effect**

Probability:
2. Probable or
3. Possible

Evidence Base:
○ **Preliminary**

Effect and Mechanism of Action

Sulfasalazine is among the medications used in standard practice for treating inflammatory bowel disease (IBD). Omega-3 fatty acids, particularly ALA, may reduce symptoms of Crohn's disease, ulcerative colitis, and other forms of IBD through multiple mechanisms of action, including modulating inflammation, reducing oxidative stress, and altering phospholipid-membrane fatty acid composition. Nevertheless, the precise mechanisms of action of ALA and fish oil in many of these

observed effects are still controversial. Concomitant therapy with both sulfasalazine and omega-3 oils may provide increased therapeutic effect through complementary actions, especially if imbalances between pro-oxidant and antioxidant mechanisms and "excess production of reactive oxygen species (ROS) by inappropriate activation of phagocytic cells" play a significant role in the pathophysiology of IBD.[226]

Research

Available data on the efficacy of omega-3 fatty acids in the treatment of IBD are conflicting, and analysis suggests that discrepancies in the findings and conclusions may result to a large degree from the different study designs, e.g., choice of placebo, insufficient washout period, differing formulations and dosages of omega-3 PUFAs.[227] Most clinical studies of omega-3 fatty acids fail to control the dietary ratio of omega-6 to omega-3, which can have profound effects on inflammatory mediators, regardless of the level of omega-3 supplementation.

Two early clinical trials involving patients with active ulcerative colitis both found that coadministration of fish oils with standard medications allowed reductions in oral corticosteroid doses. However, they arrived at partly divergent conclusions as to whether the omega-3 fatty acids reduced disease markers and enhanced therapeutic outcomes and which patient populations displayed stronger responses. In a randomized, blinded, controlled study involving 87 patients, Hawthorne et al.[228] administered "20 ml HiEPA fish oil as [the] triglyceride (4.5 g of [total] eicosapentaenoic acid) or olive oil placebo daily" for 1 year, "in addition to standard drug therapy." The investigators determined that fish oil administration "significantly increased the eicosapentaenoic acid content of rectal mucosa to 3.2% of total fatty acids at six months, compared with 0.63% for patients on olive oil," as well as "increased synthesis of leukotriene B5, and 53% suppression of leukotriene B4 synthesis by ionophore-stimulated neutrophils." Overall, they reported "measurable, but only limited clinical benefit," with "a significant reduction in corticosteroid requirement after one and two months treatment" in "patients entering the trial in relapse (n = 53)," and "a trend towards achieving remission (off corticosteroids) faster in the patients on fish oil, although differences were not [statistically] significant." However, in "patients in remission at trial entry or during the trial (n = 69), there was no significant difference in the rate of relapse by log rank analysis." Thus, the authors concluded that fish oil coadministration "produces a modest corticosteroid sparing effect in active disease, but there is no benefit in maintenance therapy," with patient response noticeably varying depending on disease activity at the onset of combination treatment.[228] In contrast, Stenson et al.[229] conducted a multicenter, randomized, double-blind, placebo-controlled, crossover trial with 4-month treatment periods (fish oil and placebo) separated by a 1-month washout involving 24 patients with active ulcerative colitis, 18 of whom completed the study. Although all subjects continued ongoing treatment with prednisone and sulfasalazine, those in the treatment group received 18 fish oil capsules, containing a total of 3.24 g EPA and 2.16 g DHA. In contrast to subjects in the placebo group, who exhibited no significant change in any variable, those administered fish oil demonstrated a "significant decrease in rectal dialysate levels of leukotriene B4 from 71.0 to 27.7 pg/mL" and "significant improvements" in acute histology index and total histology index, "as well as significant weight gain," a desired outcome in this patient population. Moreover, among the seven patients who received concurrent treatment with prednisone, "the mean prednisone dose decreased from 12.9 mg/d to 6.1 mg/d" during the fish oil supplementation period but "rose from 10.4 mg/d to 12.9 mg/d during the placebo diet period."[229]

Dichi et al.[230] compared the effects of omega-3 fatty acids and sulfasalazine in treatment of ulcerative colitis (UC) in a randomized crossover design trial involving 10 patients (five male, five female) with mild to moderate active UC. Subjects received either sulfasalazine (2 g/day) or omega-3 fatty acids (5.4 g/day) for 2 months. The authors reported that treatment with "omega-3 fatty acids resulted in greater disease activity as detected by a significant increase in platelet count, erythrocyte sedimentation rate, C-reactive protein, and total fecal nitrogen excretion." They concluded that "treatment with sulfasalazine is superior to treatment with omega-3 fatty acids in patients with mild to moderate active ulcerative colitis."[230] Subsequently, Barbosa[226] and members of the previous research team conducted a clinical trial using a randomized crossover design and involving nine patients (seven female and two male) with mild or moderately active UC. They investigated the effect of adding 4.5 g/day fish oil omega-3 fatty acids (or placebo) to their usual medication of sulfasalazine (2 g/day) for 2-month treatment periods separated by 2 months, when they received only sulfasalazine. Using nine healthy individuals as control subjects to compare oxidative stress status, the investigators demonstrated oxidative stress in patients "by significant decreases in TRAP and LPI levels, increased chemiluminescence induced by t-BuOOH, and higher SOD activity." Notably, treatment with "fish oil omega-3 fatty acids reverted the chemiluminescence induced by t-BuOOH and LPI to baseline levels but that did not occur when patients received only sulfasalazine." The authors interpreted their findings to indicate "plasma oxidative stress occurs in patients with UC, and there was a significant decrease when the patients used sulfasalazine plus fish oil omega-3 fatty acids." However, despite observed reductions in oxidative stress, "there was no improvement in most laboratory indicators, sigmoidoscopy, and histology scores." They concluded that "omega-3 fatty acids may act as free radical scavengers protecting the patients against the overall effect of oxidative stress."[226] The clinical implications of this effect, however, remain unclear.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Health care professionals treating individuals with inflammatory bowel conditions are advised to consider omega-3 PUFA therapy as either an independent intervention or as a complement to sulfasalazine, oral corticosteroids, or other anti-inflammatory agents. Although the available evidence is still preliminary and findings are mixed in some areas, the evidence from clinical trials generally indicates that fish oil, especially purified forms and time-release preparations, can enhance conventional therapies through symptom reduction and reduced medication requirements. Further research through well-designed, adequately powered clinical trials appears warranted. In studies of all pathophysiology that involves inflammation, an attempt should be made to control and standardize the omega-6 fat content of the diets within the clinical trial, because this may be a major confounder of clinical outcomes.

Dosing will depend on the type of omega-3 PUFA administered, the formulation and preparation, concomitant medications and doses, and individual patient characteristics. Standard fish oil formulations may contribute to abdominal bloating, flatulence, diarrhea, or other adverse GI effects similar to those of IBD. Time-release preparations of omega-3 fatty acids may be better tolerated in individuals with IBD.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Amphetamines and Related Stimulant Medications

Amphetamine (amphetamine aspartate monohydrate, amphetamine sulfate; dextroamphetamine); dextroamphetamine saccharate, dextroamphetamine sulfate; D-amphetamine, Dexedrine).
Methylphenidate (Metadate, Methylin, Ritalin, Ritalin-SR; Concerta).
Combination drug: Amphetamine and dextroamphetamine (Adderall; dexamphetamine).

Dopamine is a neurotransmitter involved in learning, attention, problem solving, and fine motor skills. DHA is a major component of neuronal membranes and is involved in the development of the mesocortical and mesolimbic dopamine systems. A deficiency of DHA may result in altered dopaminergic functioning.[10] The interrelatedness is currently being explored.

Anecdotal reports from some clinicians suggest that coadministering omega-3 fatty acids with conventional mixed-amphetamine therapy may enhance therapeutic effects in the treatment of individuals with attention deficit–hyperactivity disorder (ADHD). Evidence from clinical trials investigating the effects of omega-3 fatty acids with amphetamines is limited and does not support conclusions at this point. Voigt et al.[231] conducted a randomized, double-blind, placebo-controlled trial involving 63 children age 6 to 12 years with ADHD already being treated with "effective maintenance therapy with stimulant medication," who received concomitant DHA (345 mg/day) or placebo for 4 months. The observed that plasma "phospholipid DHA content of the DHA-supplemented group was 2.6-fold higher at the end of the study than that of the placebo group." However, using a variety of assessments, "there was no statistically significant improvement in any objective or subjective measure of ADHD symptoms," and it was concluded that such additional nutrient support "does not decrease symptoms of ADHD."

Antihypertensive Medications

Antihypertensive Medications

Evidence as to the hypotensive activity of fish oil is mixed, and use in clinical practice for treatment of hypertension is controversial.[42,232-237] Nevertheless, findings from several clinical trials indicates that a modest reduction in blood pressure from intake of omega-3 fatty acids seems likely.[238-244] Dose-dependent reductions in blood pressure of 2 to 5 mm Hg have been observed, with DHA exerting greater effects than EPA.[240,245] In a 6-week, double-blind, placebo-controlled involving 59 overweight men, Mori et al.[243] found that DHA, but not EPA, lowers ambulatory blood pressure and heart rate in humans. The ALA in flaxseed may theoretically also lower blood pressure.

The lack of a direct body of research focusing on coadministration and interactions has lead to speculative extrapolations and sometimes unreasonably foreboding warning that concomitant use of omega-3 PUFAs and standard antihypertensive medications could produce excessive reductions in blood pressure. The implied notion that such beneficial changes would be unnoticed and inherently dangerous verges on irresponsibly alarmist. Responsible implementation of integrative therapeutic strategies in the treatment of hypertension necessarily involves patient education, self-monitoring of blood pressure, and professional supervision. Nevertheless, caution is warranted in patients with hypotension or in those taking blood pressure–lowering medications without informing their prescribing physician of other interventions, pharmacological or otherwise.

Atypical Antipsychotics

Aripiprazole (Abilify, Abilitat), clozapine (Clozaril), olanzapine (Symbyax, Zyprexa), quetiapine (Seroquel), risperidone (Risperdal), ziprasidone (Geodon).

Numerous studies and a range of clinical experience during the past 30 years suggest the potential of omega-3 fatty acid therapy in the treatment of individuals diagnosed with schizophrenia.[84,223,246-257] Most patients are already being treated with atypical antipsychotic and/or neuroleptic medications. By reversing deficiency of EFAs and prostaglandins, positively influencing concentrations of AA, reducing oxidative damage, and other effects, the intake of fish oils or other nutrient sources can support healthy membrane and nerve function. Horrobin[252] noted that in "patients with schizophrenia, treatment with eicosapentaenoic acid (EPA) produced clinical improvement, but that improvement was greater at a dose of 2 g/day than at 4 g/day. The improvement was not significantly correlated with changes in either EPA or docosahexaenoic acid (DHA) but was highly significantly positively correlated with rises in red cell membrane AA." Further research through well-designed clinical trials specifically focusing on synergistic strategies appears warranted.

Bile Acid Sequestrants

Cholestyramine (Locholest, Prevalite, Questran), colesevelam (WelChol), colestipol (Colestid).

Bile acid resins and omega-3 fatty acids both reduce triglyceride levels, so an additive or synergistic effect might be reasonably predicted with their concomitant administration. However, a more comprehensive strategy will be necessary in treating many individuals given the tendency of fish oil to elevate LDL concentrations, although these changes typically range from negligible to slight, but occasionally can be substantial.

The primary mechanism of action employed by bile acid sequestrants involves inhibiting the absorption of fats and fat-soluble nutrients, both beneficial and problematic. This activity inherently impairs the bioavailability of omega-3 fatty acids and suggests that coadministration of fish oil preparations and a bile acid sequestrant would require separating intake of omega-3s (as well as fat-soluble vitamins) from the drug by at least 2 hours.

Available evidence suggests synergistic combinations of multiple nutrient and pharmaceutical combinations for the personalized treatment of dyslipidemias and the need for further investigation into efficacy and safety, dosage, and sequencing strategies.

Fibrates

Bezafibrate (Bezalip), ciprofibrate (Modalim), clofibrate (Atromid-S), fenofibrate (Lofibra, Tricor, Triglide), gemfibrozil (Apo-Gemfibrozil, Lopid, Novo-Gemfibrozil).

Omega-3 fatty acids may cause small elevations in LDL concentrations while lowering triglyceride (TG) levels. Fish oils also reduce inflammation and oxidative damage while enhancing arterial wall pliability. Consequently, the concomitant administration of omega-3 fatty acids may enhance the TG-lowering effects of fibrates, as well as nicotinic acid or resins.

The effects of this presumed interaction are generally accepted as self-evident in the secondary medical literature, although evidence from clinical trials directly investigating

coadministration of fibrates and omega-3 fatty acids in relevant patient populations is lacking. In a single trial comparing treatment options for hypertriglyceridemia, van Dam et al.[258] found that both omega-3 "fatty acids and gemfibrozil markedly decreased TG levels in patients with severe hypertriglyceridaemia," but that gemfibrozil "decreased TG levels and increased HDL-C significantly more than n-3 fatty acids." However, in a review of data on the efficacy and safety of different antilipidemic agents and diets on mortality, Studer et al.[102] cautioned that "any potential reduction in cardiac mortality from fibrates is offset by an increased risk of death from noncardiovascular causes."

Physicians treating patient with hypertriglyceridemia can consider omega-3 fatty acids of probable therapeutic benefit, both independently and in conjunction with standard antihyperlipidemic medications such as fibrates. This is consistent with the broad body of literature showing that higher consumption of omega-3 fatty acids correlated with a lower risk of coronary heart disease and nonfatal myocardial infarction. Shifting the dietary omega-6 to omega-3 ratio by increasing omega-3 sources and reducing omega-6 sources may also benefit several cardiovascular risk parameters. Omega-3 fatty acids have an excellent safety profile at usual doses and can be used by most patients with minimal supervision and regular lipid monitoring. However, a comprehensive strategic approach under professional supervision will be required in patient with elevated LDL levels because fish oil may cause small elevations in LDL that contravene, to a limited but largely undetermined degree, the effects of statin therapy.

Heparin and Other Injectable Anticoagulants

Heparin and Other Injectable Anticoagluants

Warnings of a potential adverse interaction between heparin and omega-3 fatty acids, particularly from fish oil, are often encountered in the derivative literature. However, direct evidence of adverse effects from clinical trials or well-qualified case reports is lacking. Further, substantive evidence as to an operative mechanism of action is insufficient and often replaced with reliance on assertions of the "blood-thinning" action of fish oil. Heparins act by augmenting the effects of antithrombin, and the newer injectable anticoagulants are direct thrombin inhibitors. There is no evidence, in vitro, preclinical, or clinical, that omega-3 fatty acids interact either with thrombin or antithrombin. Given the mild antiplatelet effects of omega-3 fatty acids, concern for increased risk of bleeding is reasonable in the relevant patient population; ungrounded speculation, however, is not an adequate substitute for clinical evidence, given the potential severity of presumed risks and the probability of coadministration among the target patient population. Further research through well-designed clinical trials is warranted, as is vigilance and systematic compilation of adverse events data. Caution, close supervision, and regular monitoring are appropriate pending clarification of these critical issues, as would be expected in such cases.

Nicotinic Acid, Niacin, Vitamin B_3

Nicotinic Acid, Niacin, Vitamin B_3

The combination of omega-3 fatty acids and niacin/nicotinic acid may produce additive or synergistic effects in lowering triglyceride levels.[259,260] A personalized and evolving pharmacological intervention with the indicated drugs and nutrients can enhance the healthy diet and regular exercise habits that form the foundation of any comprehensive program of cardiovascular risk reduction and therapeutic intervention.

Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)

COX-1 inhibitors: Diclofenac (Cataflam, Voltaren), diclofenac and misoprostol (Arthrotec), diflunisal (Dolobid), etodolac (Lodine), fenoprofen (Dalfon), furbiprofen (Ansaid), ibuprofen (Advil, Excedrin IB, Motrin, Motrin IB, Nuprin, Pedia Care Fever Drops, Provel, Rufen; combination drug: hydrocodone and ibuprofen (Reprexain, Vicoprofen); indomethacin (Indocin, Indocin-SR), ketoprofen (Orudis, Oruvail), ketorolac (Acular ophthalmic, Toradol), meclofenamate (Meclomen), mefenamic acid (Ponstel), meloxicam (Mobic), nabumetone (Relafen), naproxen (Anaprox, Naprosyn), oxaprozin (Daypro), piroxicam (Feldene), salsalate (salicylic acid; Amigesic, Disalcid, Marthritic, Mono Gesic, Salflex, Salsitab), sulindac (Clinoril), tolmetin (Tolectin).

COX-2 inhibitor: Celecoxib (Celebrex)

Omega-3 fatty acids possess many properties that might be protective against the adverse effects of NSAIDs on gastric and gut mucosa and thus reduce the risk of drug-induced ulcers. Using a rodent model, al-Harbi et al.[261] found that acute administration of fish oil (5 and 10 mL/kg body weight) significantly protected the gastric mucosa against ulcers induced by NSAIDs, reserpine, and necrotizing agents. Such activity is reasonable and consistent with known pharmacological activity of omega-3 fatty acids, and adverse effects are improbable based on current knowledge. However, well-designed clinical trials are necessary before substantive conclusions can be made as to possible protective benefits against NSAID-induced ulcerative damage in humans.

Oral Hypoglycemic Agents and Insulin

Chlorpropamide (Diabinese), glimepiride (Amaryl), glipizide (Glucotrol; Glucotrol XL), glyburide (glibenclamide; Diabeta, Glynase, Glynase Prestab, Micronase, Pres Tab), insulin (animal-source insulin: Iletin; human analog insulin: Humanlog; human insulin: Humulin, Novolin, NovoRapid, Oralin), metformin (Glucophage), tolazamide (Tolinase), tolbutamide (Orinase, Tol-Tab); combination drugs: glipizide and metformin (Metaglip); glyburide and metformin (Glucovance).

Hypertriglyceridemia is associated with cardiovascular disease in diabetes, and the relevance of fish oil therapy in such populations initially appears as highly indicated. For example, as early as 1988, Schectman et al.[262] compared the effects of 4.0 and 7.5 g of omega-3 fatty acids in fish oil with a placebo of 12 g safflower oil over 1 month in a single-blind crossover design and concluded that "in NIDDM patients, dietary supplementation with omega-3 fatty acids induces a reduction in total plasma and VLDL triglyceride levels."

Research investigating the effects of omega-3 fatty acids on blood glucose levels in type 2 diabetic persons report mixed but generally favorable findings. Overall, despite some reports of slight elevations in fasting blood glucose levels, the use of fish oil does not appear inherently to cause persistent elevations in blood glucose levels in type 2 diabetic individuals.

In response to preliminary data suggesting that fish oil may impair glycemic control in individuals with NIDDM, Dunstan et al.[72] conducted a controlled, 8-week trial to examine the effects of moderate aerobic exercise and a low-fat diet, including fish, on serum lipids and glycemic control in dyslipidemic NIDDM patients. The investigators randomly assigned 55 "sedentary NIDDM subjects (with serum triglycerides > 1.8 mmol/L and/or HDL cholesterol < 1.0 mmol/L) to a low-fat diet (30% daily energy intake) with or without one

fish meal daily (3.6 g omega-3/day) and further randomized to a moderate (55%-65% VO_2max) or light (heart rate < 100 bpm) exercise program." They reported that among the 49 subjects who completed the study, "moderate exercise improved aerobic fitness (VO_2max) by 12%," and fish consumption reduced triglycerides (0.80 mmol/L) and HDL_3 cholesterol (0.05 mmol/L) and increased HDL_2 cholesterol. Based on these findings, the authors concluded that a "reduced fat diet incorporating one daily fish meal reduces serum triglycerides and increases HDL_2 cholesterol in dyslipidemic NIDDM patients" and noted that potential omega-3-induced "deterioration in glycemic control can be prevented by a concomitant program of moderate exercise."[72]

Similarly, Sheehan et al.[59] conducted a trial in which subjects received 20 g fish oil daily, and usual daily fiber intake was increased with a 15-g pectin supplement at midpoint. They not only observed the expected beneficial effects on triacylglycerol and VLDL cholesterol levels, but also found that "diabetic control was maintained" during the 12-week study, and that total and LDL cholesterol concentrations "decreased significantly" with concomitant fish oil treatment and high fiber intake.

Administration of fish oil for dyslipidemia in patients with type 2 diabetes does not appear to result in significant long-term adverse effects. In two papers published in the late 1980s, Stacpoole et al.[51,263] reported dose-response effects of dietary fish oil on carbohydrate and lipid metabolism in hypertriglyceridemia and concluded that the increased insulin needs observed in some diabetic patients on long-term fish oil therapy were most likely derived from other dietary changes or weight gain. In an early review article, Harris[56] declared that the "safety of fish oils was also supported in these studies because problems with excessive bleeding and worsening glycemic control did not materialize." Subsequently, in a 1998 meta-analysis, Friedberg et al.[264] concluded that the "use of fish oil has no adverse affects on HbA_{1c} in diabetic subjects and lowers triglyceride levels effectively by almost 30%," even though "this may be accompanied by a slight increase in LDL cholesterol concentration." Two years later, in a quantitative systematic review of the effects of fish oil administration on lipid levels and glycemic control in patients with type 2 diabetes, Montori et al.[213] concluded that fish oil administration in individuals with type 2 diabetes "lowers triglycerides, raises LDL cholesterol, and has no statistically significant effect on glycemic control." They suggested, however, that trials "with hard clinical end points are needed."

In a randomized, controlled trial investigating the effects of omega-3 PUFAs on glucose homeostasis and blood pressure in patients with essential hypertension, Toft et al.[265] concluded that fish oil, "in doses that reduce blood pressure and lipid levels in hypertensive persons, does not adversely affect glucose metabolism."

The occurrence of a clinically significant adverse interaction between fish oil and medications for glucose control appears improbable for most individuals at usual dosage levels. Overall, the literature suggests that adverse effects on glucose control caused by fish oil administration in type 2 diabetic individuals is possible but uncommon and possibly self-limiting. Further, the ability of aerobic exercise and increased fiber intake to neutralize adverse effects associated with fish oil intake suggests that other lifestyle interventions typical within a comprehensive integrative approach to management of type 2 diabetes will also serve to enhance the benefits and moderate the possible adverse effects of fish oil therapy. Notably, no clinical trials or qualified case reports have been presented as supporting the hypothesis that fish oil coadministration might impair the therapeutic activity of oral hypoglycemic medications (or insulin). Nevertheless, health care professionals treating patients with type 2 diabetes will want to advise and support healthy lifestyle and dietary changes and monitor any significant changes in diet or intake of nutrients such as fish oil or flaxseed at therapeutic doses.

Oral Vitamin K Antagonist Anticoagulants

Anisindione (Miradon), dicumarol, ethyl biscoumacetate (Tromexan), nicoumalone (acenocoumarol; Acitrom, Sintrom), phenindione (Dindevan), phenprocoumon (Jarsin, Marcumar), warfarin (Coumadin, Marevan, Warfilone).

Omega-3 fatty acids may increase the anticoagulant properties of warfarin and related anticoagulant drugs, although the frequency and character of a clinically significant interaction appears to be less certain and severe than suggested in most of the secondary literature. Intake of 3 g or greater of omega-3 fatty acids daily may increase the risk of spontaneous bleeding, although there is little evidence of significant bleeding risk at lower doses.[48,78] When combined with dipyridamole, omega-3 fatty acid intake may have positive synergistic effects for the protection against heart diseases and stroke because this combination acts to reduce thrombosis, most likely through anti-aggregatory effects on platelets.[266]

In a 1994 paper, Weksler[47] proposed that omega-3 fatty acids, at very high intake levels, appeared to have multiple antithrombotic effects. However, a subsequent study of hemostatic factors by Archer et al.[49] considered race, gender, age, and weight and systematically examined the effects of dietary ALA, EPA, and DHA in the Coronary Artery Risk Development in Young Adults (CARDIA) Study. They reported that "no significant associations were observed between those who consumed no fish versus those who consumed the highest level of dietary fish with respect to fibrinogen, factor VIII, or von Willebrand factor for any race-sex group. Comparisons of tertile 1 versus tertile 3 for dietary linolenic acid, eicosapentaenoic acid, and docosahexaenoic acid were also not significantly associated with fibrinogen, factor VII, factor VIII, or von Willebrand factor for any race-sex group." The authors concluded that their "data suggest that customary intakes of fish and n-3 fatty acids in populations that generally do not consume large amounts of these food items are not associated with [changes in] these hemostatic factors."[49] The amounts reported in this investigation were not the high doses used in much contemporary research, suggesting that anticoagulant effects reported in many studies may be dose dependent.

In a 2004 paper, Vanschoonbeek et al.[267] presented their findings from a study of the variable hypocoagulant effect of fish oil intake in humans, particularly focusing on modulation of fibrinogen level and thrombin generation. For 4 weeks they administered 3.0 g omega-3 PUFAs daily to 25 healthy, borderline-overweight males. They observed that fish oil intake "reduced plasma triglycerides and lowered platelet integrin activation, as well as plasma levels of fibrinogen and factor V, but had no effect on vitamin K–dependent coagulation factors." Notably, fish oil intake "reduced thrombin generation in the presence and absence of platelets" in a manner "correlated with the fish oil effect on fibrinogen and factor V levels" and "clustered around subjects with high fibrinogen carrying a structural fibrinogen alpha-chain polymorphism." The authors concluded that dietary "omega-3 PUFAs provoke a hypocoagulant, vitamin K–independent effect in humans, the degree of which may depend on [preexisting] fibrinogen level."[267]

More research is needed in this area to provide conclusive evidence of the omega-3 fatty acid interrelationship to antithrombotic effects and potential interaction with anticoagulant medications.

Health care professionals treating individuals with a history of or increased risk of stroke or clotting disorders or being treated with anticoagulant medications for other reasons are advised to conduct a frank discussion regarding nutrient, herb, and medication intake and thoroughly inventory all agents. Close supervision is usually unnecessary for most patients using omega-3 oils at typical doses, but regular international normalized ratio (INR) monitoring and dose titration are always critical in patients receiving oral vitamin K antagonist anticoagulants, especially with introduction, withdrawal, or change in dose of any pharmaceutical, nutraceutical, or herbal agent.

Salicylates and Related Antiplatelet Medications, Including Acetylsalicylic Acid and Monoclonal Antibody Antiplatelet Agents

Antiplatelet thromboprophylactics: Acetylsalicylic acid (acetosal, acetyl salicylic acid, ASA, salicylsalicylic acid; Arthritis Foundation Pain Reliever, Ascriptin, Aspergum, Asprimox, Bayer Aspirin, Bayer Buffered Aspirin, Bayer Low Adult Strength, Bufferin, Buffex, Cama Arthritis Pain Reliever, Easprin, Ecotrin, Ecotrin Low Adult Strength, Empirin, Extra Strength Adprin-B, Extra Strength Bayer Enteric 500 Aspirin, Extra Strength Bayer Plus, Halfprin 81, Heartline, Regular Strength Bayer Enteric 500 Aspirin, St. Joseph Adult Chewable Aspirin, ZORprin); combination drugs: ASA and caffeine (Anacin); ASA, caffeine, and propoxyphene (Darvon Compound); ASA and carisoprodol (Soma Compound); ASA, codeine, and carisoprodol (Soma Compound with Codeine); ASA and codeine (Empirin with Codeine); ASA, codeine, butalbital, and caffeine (Fiorinal); ASA and extended-release dipyridamole (Aggrenox, Asasantin); aminosalicylic acid: 5-amino-2-hydroxybenzoic acid, 5-ASA, mesalamine, asacol, salofalk, pentasa, mesalazine, m-aminosalicylic acid, para-aminosalicylic acid.
Similar properties but evidence lacking for extrapolation: Monoclonal antibody antiplatelet agents: Abciximab (ReoPro), eptifibatide (Integrelin), tirofiban (Aggrastat).

Fish oil improves blood flow characteristics by replacing other RBC and endothelial cell membrane fatty acids with omega-3 fats. This shift, along with other factors, reduces platelet-derived growth factor (PDGF), decreases platelet aggregation, inhibits the expression of vascular adhesion molecules, and stimulates relaxation of endothelial cells in the vasculature.[268] The multiple antithrombotic and eicosanoid-modifying effects of omega-3 PUFAs may increase the risk of bleeding under certain conditions, especially at higher dosage levels, but are probably also an important factor in the beneficial effect of dietary fish oil observed on cardiovascular disease.[47-49,108,267,269,270]

Omega-3 fatty acids could theoretically increase the antiplatelet aggregation effects of aspirin and other antiplatelet agents in a bimodal fashion, that is, beneficial with atherosclerosis and risk of clotting in a cerebral or coronary vessel, but problematic with bleeding disorders or in patients taking oral or injectable anticoagulants. Although the effects of omega-3 fatty acids on hemostatic variables have been widely discussed in the scientific literature for many years, the evidence supporting a pattern of clinically significant adverse interactions is lacking. The combination of aspirin and omega-3 fatty acids may be beneficial under certain circumstances (e.g., heart disease) but problematic in other conditions (e.g., warfarin therapy, von Willebrand's disease). A consensus has largely been achieved as to the modulation of fibrinogen level and thrombin generation and resultant variable hypocoagulant effect of fish oil intake in humans. However, the clinical implications of these findings remain controversial, and broad generalizations remain elusive, particularly with regard to the little-researched area of interactions between omega-3 oils and antiplatelet agents.

Minimal evidence suggests that fish oil, flaxseed, and flaxseed oil may cause increased risk of bleeding complications. The secondary literature has made numerous declarations, usually without primary supporting citations, that intake of 3 g or greater of omega-3 fatty acids daily may increase the risk of bleeding; there is general agreement that significant bleeding is improbable at lower doses in most patients.[47-49]

In a double-blind, randomized, crossover study involving six healthy volunteers, Iacoviello et al.[271] observed that the combination of low-dose aspirin (40 mg/day) and omega-3 fatty acids (5.3 g/day) modulated the fibrinolytic response to venous occlusion and could be therapeutic in the treatment of some forms of coronary artery disease.

Fish oil appears to modulate inflammation in the GI tract in ways that might mitigate damage to the mucosal tissues inherent to use of salicylates, especially with chronic administration, and suggest a possible beneficial interaction. Although research concerning the benefits of omega-3 rich oils alone with Crohn's disease is controversial, some studies report a pattern of improvement in patients treated with fish oil.[272-274] A double-blind, randomized, placebo-controlled trial involving pediatric patients suggests that administration of omega-3 fatty acids, in combination with mesalazine (amino-salicylic acid), acts as an effective measure for maintaining remission of Crohn's disease. The synergistic combination serves to strengthen the respective inhibitory roles within the anti-inflammatory cascade.[275] However, although the full range of effects exerted by fish oil on inflammation remains unclear, available evidence indicates that fish oil does not appear to affect C-reactive protein levels.[214]

Given the large number of individuals who use aspirin on a regular or occasional basis and the broad use of fish oil and flax, a number of qualified case reports of interactions events would be expected. The absence of such documented events supports the proposition that, pending substantive corroboration, any such interaction should be considered preliminary and theoretical and its clinical significance improbable. On the other hand, however, the occurrence of an interaction may be widespread but its effects negligible or beneficial, and thus unlikely to appear in published case reports.

Health care professionals treating individuals at risk for bleeding disorders or related complications are advised to conduct a frank discussion regarding nutrient and medication intake and thoroughly inventory all agents. Close supervision is usually unnecessary for most patients using omega-3 oils at typical doses, but regular monitoring would be judicious in any patients at risk for excessive bleeding.

NUTRIENT-NUTRIENT INTERACTIONS

Arginine

In a 6-month, prospective, randomized, double-blind controlled study involving 64 HIV-infected outpatients (with CD4 lymphocyte count $\geq 100 \times 10^6$/L), Pichard et al.[276] found that the addition of arginine and omega-3 fatty acids did not improve immunological parameters compared with a group receiving only the base multinutrient oral formulation; body weight increased in both groups.[276] The synergy between

omega-3 fatty acids and arginine in supporting wound healing and tissue regeneration warrants further research and development of evidence-based clinical guidelines.

Iron and Vitamin B_6

The delta-6-desaturase enzyme complex is central to PUFA metabolism. The delta-6-desaturase enzyme complex requires iron for its activity. The transmethylation reaction of proteins is impacted by vitamin B_6 deficiency. Consequently, deficiencies of iron or vitamin B_6 can exert an adverse effect on PUFA metabolism.

In a trial involving 59 subjects, Krajcovicova-Kudlackova et al.[277] determined plasma PUFA content in "apparently healthy subjects of the general population with no consumption of fish" and low vitamin B_6 serum levels (<3 µg/L) or with low iron serum levels (men: <12 µmol/L; women: <10 µmol/L) and compared to a control group with normal vitamin B_6 and iron serum levels (i.e., within reference range). They observed that subjects in groups "with low vitamin B_6 and low iron levels," conversion of ALA to EPA and DHA was "significantly reduced." The authors noted that the "inhibition effect on fatty acid synthesis was more pronounced in subjects with low iron levels than in those with low vitamin B_6 levels" and that "conversion indices correlated significantly positively with vitamin B_6 or iron levels."

This reported interaction between omega-3 fats and other nutrients is only relevant to individuals on vegan diets who do not consume EPA and/or DHA directly through either fish oil or algae-derived DHA. The observed patterns may relate to cognitive, cardiovascular, and other benefits and risks associated with fish oil intake. Further investigation appears warranted.

Vitamin E

The apparent interactions between omega-3 fatty acids and vitamin E are complex, paradoxical, and insufficiently understood to support any firm conclusions. High dietary intake of PUFAs can induce decreased vitamin E levels.[278] Vitamin E is usually added to fish oil products to protect against degeneration caused by oxidative damage and in response to concerns that long-term use of fish oil at high dose levels may deplete vitamin E. Subsequently, the resulting product sometimes is considered a potential source of excessive vitamin E because of potential accumulation of this fat-soluble nutrient. Similarly, the "blood-thinning" effects of these two important nutrients may be of concern in patients at risk for or diagnosed with bleeding tendencies, but solid evidence of adverse additive effects is apparently lacking. The clinical significance of these proposed risks is belied by the apparent lack of large numbers of adverse events reports relative to the sizable number of individuals consuming these nutrients regularly. Nevertheless, the issues raised may deserve further research and could lead to deeper knowledge of these nutrients, their actions and effects, and any possible interactions (beneficial or adverse) or complications.

Vitamin E has also been shown to counteract the elevations in blood glucose sometimes seen with initiation of fish oil intake in individuals with type 2 diabetes.[71]

HERB-NUTRIENT INTERACTIONS

Ginkgo

Ginkgo *(Ginkgo biloba)*

Ginkgo biloba, as well as other botanicals such as ginger and feverfew, demonstrates antiplatelet effects and thus may increase the bleeding tendency associated with fish oil. However, no supporting clinical studies or qualified case reports have documented such an interaction as clinically significant. Nevertheless, further research may be warranted given the high probability of concomitant use, especially self-prescribed by patients outside professional supervision.

Ginseng, Chinese/Korean

Chinese/Korean Ginseng *(Panax ginseng)*

Based on presumptive and usually unarticulated mechanisms of action, claims that ginseng may increase the bleeding tendency associated with fish oil are occasionally found in secondary and derivative literature. However, substantive evidence from qualified case reports or clinical trials is lacking.

The 279 citations for this monograph, as well as additional reference literature, are located under Omega-3 Fatty Acids on the CD at the back of the book.

PABA

Nutrient Name: PABA (para-aminobenzoic acid).
Synonyms: Para-amino benzoic acid, p-aminobenzoic acid, pABA; Potaba.
Related Substance: Para-aminobenzoate.

Physiology and Function

Para-aminobenzoic acid (PABA) is a member of the vitamin-B complex but is not generally recognized as an official vitamin.

NUTRIENT IN CLINICAL PRACTICE

Possible Uses

Arthritis, dermatitis herpetiformis, dermatomyositis, hair graying, infertility (female), insomnia, pemphigus, Peyronie's disease, scleroderma, sunscreen (topical UV obstruction), vitiligo.

Deficiency Symptoms

None established.

Dietary Sources

Whole grains and foods of animal origin, particularly brewer's yeast, wheat germ, bran, and liver.

Nutrient Preparations Available

As a single-ingredient over-the-counter nutraceutical, PABA is usually 100 to 500 mg per dose. More often, small amounts of PABA may be contained within multivitamin or B-complex formulations. Potaba, the potassium salt of PABA, is available by prescription.

Dosage Forms Available

Capsule, tablet.

Dosage Range

Dietary: None established.
Supplemental/Maintenance: Dietary requirement not established.
Pharmacological/Therapeutic: Dosage in clinical trial has ranged from 300 mg to 12 g per day.
Toxic: Toxicity possible with greater than 400 mg PABA; extended use of several grams daily is more likely the range necessary to induce adverse symptoms.

SAFETY PROFILE

Overview

PABA is generally considered to be safe and free of adverse effects at doses up to 400 mg, but minor adverse effects have been reported at doses as low as 30 mg/day. Some symptoms may be attributable to its mildly acidic nature when taken orally; these generally do not occur with the potassium salt of PABA (Potaba). Most reports of significant adverse effects, such as vitiligo or elevated liver enzymes, have been associated with daily doses of 8 to 12 g daily.[1,2] Deaths have been reported at 20 g/day in children and as high as 48 g/day (for 6 days, followed by 7 months at 8 g/day).[3,4]

Nutrient Adverse Effects

Dermatitis, fever, hypoglycemia, itching, liver toxicity, loss of appetite, nausea, vomiting.

Contraindications

Individuals taking sulfonamides and sulfones.

INTERACTIONS REVIEW

Strategic Considerations

Increased PABA levels, resulting from increased endogenous production or increased exogenous (nutraceutical) sources, can cause increased resistance to sulfa drugs (sulfonamides and sulfones) through its effect on folic acid pathways. Patients receiving long-term sulfa drugs (e.g., HIV/AIDS patients on sulfa prophylaxis for *Pneumocystis*) are at risk for folic acid deficiencies; for example, megaloblastic anemia is a possible complication. Homocysteine levels often rise with ordinary courses of sulfa antibiotics.

NUTRIENT-DRUG INTERACTIONS

Sulfonamides, Sulfones, and Related Sulfa Antibiotics

Evidence: Dapsone (DDS, diaminodiphenylsulphone; Aczone Gel, Avlosulfon), sulfasalazine (salazosulfapyridine, salicylazosulfapyridine, suphasalazine; Apo-Sulfasalazine, Azulfidine, Azulfidine EN-Tabs, PMS-Sulfasalazine, Salazopyrin, Salazopyrin EN-Tabs, SAS); combination drug: sulfamethoxazole and trimethoprim (cotrimoxazole, co-trimoxazole, SXT, TMP-SMX, TMP-sulfa; Bactrim, Bactrim DS, Cotrim, Septra, Septra DS, Sulfatrim, Uroplus); sulfamethoxazole (Gantanol). Extrapolated, based on similar properties: Sodium sulfacetamide (AK-Sulf, Bleph-10, Sodium Sulamyd), sulfanilamide (AVC), sulfisoxazole (Gantrisin), triple sulfa (Sultrin Triple Sulfa).

Effect and Mechanism of Action

Sulfones and sulfonamides exert their antimicrobial action by competitively displacing para-aminobenzoic acid (PABA) from its binding site on 7,8-dihydropteroate synthase (DHPS), an enzyme critical for de novo synthesis of folic acid by many pathogenic microorganisms. Specifically, DHPS catalyzes the condensation of PABA with 6-hydroxymethyl-7,

8-dihydropterin-pyrophosphate to form 7,8-dihydropteroate and pyrophosphate. Consequently, sulfonamide and sulfone drugs cause cell death by depleting the folate pool necessary to microbial growth. Furthermore, extended use of sulfa drugs can result in depletion of PABA as well as depletion of folate and subsequent elevation of homocysteine. Conscientious physicians are advised to coadminister folic acid when they prescribe sulfa drugs.

Research

The phenomenon of sulfonamide-resistant infections was first discussed in the late 1960s, but the mechanism of action underlying the effectiveness of sulfa drugs only gradually became known, with increasing knowledge of the interaction between PABA and this important class of antibiotics.

In a 1966 clinical trial involving 39 volunteers subjected to mosquito-borne malaria infections, Degowin et al.[5] observed that PABA intake impaired the antimalarial activity of dapsone (DDS) against chloroquine-resistant *Plasmodium falciparum*. The five subjects receiving both PABA (1 g four times daily) and dapsone (25 mg daily) demonstrated acute malaria, in contrast to subjects given dapsone only, before and for 1 month after exposure, in whom malaria was suppressed. Irshaid et al.[6] (1993) found that PABA substantially inhibited the acetylation of dapsone (DDS) by whole blood taken from both slow and rapid acetylators. In 1994, McConkey et al.[7] showed that auxotrophs of *P. falciparum* were dependent on *p*-aminobenzoic acid for growth. That same year, Voeller et al.[8] described the interaction of *Pneumocystis carinii* DHPS with sulfonamides and diaminodiphenyl sulfone (dapsone) and clarified that DHPS is the target enzyme for the sulfonamide compounds. In a subsequent study of the pharmacokinetic parameters of elimination of sulfamoyl benzoic acids, sulfonamides, and penicillins via tubular secretion, Ehlert et al.[9] observed inhibition of the conjugation of PABA with glycine in vitro.

In a 1999 paper, Vinnicombe and Derrick[10] investigated the enzymatic mechanism and sulfonamide inhibition of DHPS from the pathogen *Streptococcus pneumoniae*. Using equilibrium binding assays, they showed that binding of the substrate PABA to DHPS was absolutely dependent on the presence of pyrophosphate, which acts as an analog of the second substrate 6-hydroxymethyl-7,8-dihydropterin pyrophosphate (DHPPP), and that the product of the reaction, dihydropteroate, was also able to bind to DHPS. Sulfonamides were capable of displacing PABA in a competitive manner. Thus, the authors determined that the specific target for sulfonamide inhibition of *S. pneumoniae* DHPS is the enzyme-DHPPP binary complex. Shortly thereafter, in an experiment using *Saccharomyces cerevisiae*, Castelli et al.[11] found that 15 sulfa drugs inhibited yeast growth in a manner indicating competition with PABA. Such competition resulted from direct addition of PABA or through increased expression of the PABA synthase gene.

Despite the axiomatic mechanism involved and the consistent evidence available in the interaction, its incidence and severity remain largely unclear.

Clinical Implications and Adaptations

Physicians prescribing sulfa drugs should advise patients to refrain from concomitant use of PABA, to avoid interference with the therapeutic activity of the medication. Although there is no known and agreed therapeutic ceiling for PABA dosing that would not interfere with sulfa therapy, daily doses greater than 100 mg twice daily are more likely to have a clinically significant effect. Whether it is also necessary to avoid B-complex or multivitamin formulas containing lower levels of PABA remains uncertain.

Further clinical research is warranted to determine the clinical significance of various dosage levels of pABA intake in relation to particular sulfa agents and respective pathogens, as well as the importance and implications of folate coadministration for patients undergoing long-term treatment with sulfones and sulfonamide antibiotics.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Chemotherapy and Radiation, Particularly Paclitaxel

Evidence: Paclitaxel (Paxene, Taxol).

Following reports that PABA might be capable of inhibiting the development of melanoma in vitro, Dr. Peter Brooks[12] and colleagues at New York University School of Medicine conducted research on highly melanotic B16F10 melanoma cells, as well as lung and breast carcinoma cells, using PABA alone and in conjunction with conventional cancer therapies. PABA alone had little effect on proliferation, but these researchers observed substantial inhibition of proliferation if the cells were treated with PABA and then treated with ionizing radiation and/or chemotherapy. Subsequent experiments with melanoma-bearing mice yielded similar results. In particular, a significant decrease in tumor progression was noted in tumors treated with PABA plus paclitaxel (Taxol) and/or ionizing radiation, compared with tumors left untreated or treated with paclitaxel alone. Although the mechanism of PABA action remains unknown, results of differential complementary DNA (cDNA) array analysis suggest that PABA upregulates cell cycle control genes and downregulates DNA repair enzymes. Such preliminary findings suggest a possible role for PABA in optimizing existing cancer therapies. These researchers have begun a clinical trial investigating concomitant administration of paclitaxel and PABA in the treatment of patients with melanoma.

Methotrexate

Methotrexate (Folex, Maxtrex, Rheumatrex).

As a dihydrofolate reductase (DHFR) inhibitor, methotrexate interferes with folic acid activation while PABA increases folate availability through its effect on DHPS. Consequently, PABA coadministration, or folic acid intake, has been found to interfere with the therapeutic activity of methotrexate in individuals being treated for cancer.[13] However, the action of methotrexate in the treatment of rheumatoid arthritis or psoriasis does not depend on folate suppression, so administration of PABA (as well as folic acid or folinic acid) is not contraindicated, even though it might lower methotrexate levels, and can be beneficial in reducing adverse effects associated with the drug.[14-21] Close supervision and regular monitoring are appropriate during any such coadministration. Further research into such concomitant therapeutic protocols is warranted.

The 21 citations for this monograph, as well as additional reference literature, are located under PABA on the CD at the back of the book.

Policosanol

Nutrient Name: Policosanol

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Acetylsalicylic acid (ASA, aspirin) Antiplatelet medications ✗✗/⊕✗/⊕⊕	Policosanol can inhibit platelet aggregation, but probability and intensity of clinically significant additive effect with antiplatelet medications are uncertain. Concomitant use could be therapeutically efficacious and enable lower drug dosage with proper management. Potential risk of excess additive effect.	Coadministration can be beneficial. May need to modify drug dosage. Monitor and titrate.
Anticoagulant medications ✗✗/⊕✗/⊕	Policosanol appears to inhibit platelet function, but not to alter coagulation parameters and is unlikely to interact with anticoagulant medications to produce an additive effect of clinical significance. Hemorrhage or inappropriate thinning are theoretically possible but have not been documented. Concomitant use could theoretically be therapeutically efficacious and enable lower drug dosage with proper management.	Coadministration may be beneficial (or potentially risky). May need to modify drug dosage. Monitor and titrate.
Beta-1 Adrenoceptor antagonists Antihypertensive medications ✗✗/⊕✗/⊕⊕	Policosanol can exert hypotensive effect, but probability and intensity of clinically significant additive effect with beta blockers are uncertain. Potential risk of additive effect and excess hypotensive action. Coadministration could be therapeutically efficacious and enable lower drug dosage with proper management.	Coadministration can be beneficial (or risky). May need to modify drug dosage. Monitor and titrate.
HMG-CoA reductase inhibitors (statins) ✗/⊕✗/⊕⊕	Both HMG-CoA reductase inhibitors and policosanol can inhibit cholesterol synthesis to varying degrees. Clinically significant additive or synergistic effect is possible, but research findings are preliminary and mixed. Concomitant use could potentially be therapeutically efficacious and enable lower statin dosage (and reduced adverse effects) with proper management, particularly within a personalized strategy. Minimal risk of detrimental additive effect.	Coadministration may be beneficial, typically within a strategy including coQ10, niacin, fish oil, and other agents. Monitor closely within context of integrative cardiovascular care. May need to modify drug dosage.

NUTRIENT DESCRIPTION

Chemistry and Form

Policosanol contains a natural mixture of eight long-chain aliphatic primary alcohols extracted from the wax of sugarcane (*Saccharum officinarum* L.). A similar complex of long-chain aliphatic alcohols can also be derived from rice bran and beeswax, although most of the existing clinical studies have been done with sugarcane-derived material. Octacosanol (18-carbon) is the predominant moiety, constituting approximately 60% of the mixture. Other important constituents include triacontanol (13%) and hexacosanol (6%). Minor components include tetracosanol, heptacocosanol, nonacosanol, dotriacontanol, and tetratriacontanol.

Physiology and Function

Policosanol decreases levels of cholesterol in serum as well as cholesterol content in various tissues, such as liver, heart, and fatty tissue. In numerous clinical trials, policosanol has demonstrated lipid-lowering efficacy comparable to statin drugs and offers the potential to suppress isoprenylation reactions much as statins do, without the attendant hepatotoxicity and other adverse effects typically associated with direct hydroxymethylglutaryl–coenzyme A (HMG-CoA) reductase inhibition. Other trials have produced less positive findings. Policosanol appears to reduce low-density lipoprotein cholesterol (LDL-C) and total cholesterol by inhibiting hepatic cholesterol synthesis before the formation of mevalonate, between the formation of acetate and mevalonate, and downregulating cellular expression of, but not directly inhibiting, HMG-CoA reductase. It also lowers LDL by enhancing the binding, uptake, and degradation of LDL-C in the endoplasmic reticulum.

Nevertheless, scientific knowledge of the exact mechanisms of policosanol's lipid-lowering activity remains incomplete and uncertain. High doses of policosanol can alter prostaglandin synthesis, lower platelet aggregation induced by arachidonic acid (AA), and inhibit proaggregatory thromboxane A_2 (TXA_2) generation induced by collagen; it does not inhibit and may increase levels of the antiaggregatory prostaglandin prostacyclin. Policosanol supports healthy endothelial function by preventing intimal thickening and smooth muscle cell proliferation while also preventing and possibly reversing atherosclerotic lesions and thrombosis. Policosanol may be active as an effective antioxidant in the cardiovascular system, particularly in preventing LDL oxidation, most likely by limiting microsomal lipid peroxidation.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Policosanol has primarily been proposed as part of a comprehensive approach to treating dyslipidemia. Some research suggests that it may be specifically effective in reducing elevated LDL-C and total cholesterol levels, particularly in type II hypercholesterolemia, including the IIa subtype (characterized by elevated total serum cholesterol and LDL-C levels), the IIb subtype (mixed hypercholesterolemia characterized by elevated total serum cholesterol, LDL-C, and triglyceride levels), and diabetes-related hypercholesterolemia. It also appears to increase levels of high-density lipoprotein cholesterol (HDL-C). Efficacy in the treatment of intermittent claudication is consistent with its known effects on platelet aggregation and endothelial function.

Historical/Ethnomedicine Precedent

Policosanol has not been used historically as an isolated nutrient.

Historical Note: Policosanol was largely developed in Cuba during the embargo that prevented access to many Western pharmaceuticals, and the initial laboratory and clinical research was done by Cuban scientists and physicians. Subsequent researchers and commentators, particularly after less successful trials, have suggested that politics may have played a role in earlier published findings of therapeutic efficacy.

Possible Uses

Dyslipidemia, hypercholesterolemia (type II), intermittent claudication, platelet aggregation.

Deficiency Symptoms

Not applicable.

Dietary Sources

Not applicable.

Dosage Forms Available

Capsule, tablet.

Source of Materials for Nutrient Preparations

Isolated constituents from sugarcane *(Saccharum officinarum)* wax; beeswax, rice bran.

Dosage Range

Adult

Dietary: Not applicable.
Supplemental/Maintenance: Not applicable.
Pharmacological/Therapeutic: 5 to 20 mg per day. A 6-month double-blind clinical trial found that daily dosages greater than 20 mg produce no significant additional cholesterol-lowering efficacy.[1] Many practitioners experienced in nutritional therapeutics advise patients to take their once-daily dose of policosanol in the evening because hepatic synthesis of cholesterol usually occurs primarily during the night.
Toxic: None reported, even at equivalent of approximately 620 times higher than the maximal recommended therapeutic dose (20 mg/day).[2]

SAFETY PROFILE

Overview

Clinical trials of policosanol lasting up to 3 years indicate that it is well tolerated and safe for most individuals at usual dosage levels.[3] Policosanol has not been associated with increases in hepatic enzymes or creatine kinase.

Nutrient Adverse Effects

General Adverse Effects

Quantifiable adverse effects include weight loss (1.8% of patients), polyuria (0.7%), and headache (0.6%). Other reported adverse effects include insomnia, somnolence, nervousness, dizziness, excitability, hypotension, hypertension, polyphagia, nausea, epigastric pain, diarrhea, constipation, erythema, pruritus, skin rash, and bleeding from the nose and gums.[4] These symptoms have been recorded in people taking policosanol; causality linking policosanol and these symptoms has not been established.

Research with Swiss mice shows no evidence of policosanol-induced carcinogenicity.[5]

Several animal studies, including rat model using doses up to 500 mg/kg, showed no evidence of significant reproductive or mutagenic toxicity.[2,6,9]

Adverse Effects Among Specific Populations

No dosage reduction is necessary in individuals with compromised hepatic function. No studies have been conducted involving individuals with compromised renal function.[4]

Pregnancy and Nursing

As of this writing, no reported adverse effects have been related to fetal development during pregnancy or to breast-fed infants. However, use during pregnancy is generally contraindicated because cholesterol and associated metabolic products are required for healthy fetal development. Likewise, administration during lactation should be discontinued because little is known about whether the product or some active metabolite is excreted in breast milk.

Infants and Children

Adequate long-term research is lacking, but no adverse effects have been reported in relation to policosanol use by children.

Contraindications

Pregnancy, breastfeeding.

Precautions and Warnings

Although potentially beneficial, concurrent use of policosanol and HMG-CoA reductase inhibitors may be inappropriate given the current lack of knowledge of policosanol's mechanism of action.

INTERACTIONS REVIEW

Strategic Considerations

Data from long-term formal studies of drug interactions, additive toxicity, or integrative therapeutics involving policosanol in humans are generally lacking. Pharmacokinetic research suggests that policosanol does not interact with drug-metabolizing processes involving the cytochrome P450 microsomal system.[2] Consequently, drug-to-drug interactions between policosanol and drugs metabolized through the cytochrome P450 hepatic system are not probable, although adverse pharmacodynamic drug-to-drug interactions cannot be excluded. Furthermore, the consistent lack of toxicity associated with sustained policosanol therapy and its proposed ability to shift lipid parameters positively and inhibit platelet aggregation significantly, without elevating liver enzymes or affecting coagulation parameters, suggest that therapeutic synergy is more likely to characterize potential interactions than is enhanced risk. Adjunctive therapies with a strong safety profile are much in demand given the wide range of uses emerging for statin medications and the widespread use of beta blockers, despite their known toxicities and risks. Thus, policosanol presents significant promise as a therapeutic agent in concert with statins,

beta blockers, or other nutritional and botanical agents to treat dyslipidiemia and support lipid homeostasis and healthy cardiovascular function.

Even though largely undertaken by a relatively small number of researchers, mostly by a single research institute in Cuba, the initial positive evidence available on policosanol provides a substantial foundation for further large, well-designed clinical trials into its efficacy and interaction patterns. In contrast to data indicating that policosanol at 5 to 40 mg per day exerts lipoprotein-lowering effects comparable to statins, Berthold et al.[10] (2006) arrived at much less convincing findings. These investigators conducted a multicenter, randomized, double-blind, placebo-controlled, parallel-group trial in Germany involving 143 patients with "hypercholesterolemia or combined hyperlipidemia having baseline low-density lipoprotein cholesterol (LDL-C) levels of at least 150 mg/dL . . . and either no or one cardiovascular risk factor other than known coronary heart disease, or baseline LDL-C levels of between 150 and 189 mg/dL . . . and two or more risk factors." After a 6-week initial open-label placebo and diet run-in phase, they randomized subjects into five groups receiving sugarcane-derived policosanol (10, 20, 40, or 80 mg daily) or placebo for a double-blind 12-week treatment phase. None of the subjects in the five treatment groups exhibited decreases in LDL-C levels more than 10% from baseline, and "no statistically significant difference between policosanol and placebo was observed." Furthermore, after this relatively short treatment period, none of the secondary outcome measures—total cholesterol, HDL-C, very-low-density lipoprotein cholesterol (VLDL-C), triglycerides, lipoprotein(a), and ratio of total or LDL-C to HDL-C, exhibited any significant effects of policosanol.[10]

In an 8-week, double-blind, randomized controlled trial, Dulin et al.[11] reported that policosanol (20 mg/day) is "ineffective" in the treatment of "mild hypercholesterolemia."

These conflicting findings indicate that long-term, well-designed studies of adequate size are warranted to determine the therapeutic efficacy of policosanol monotherapy and suggest whether its role as a component of a more comprehensive protocol may be more effective. It should be noted that Berthold's study[10] of 143 patients randomized into five groups is very small (< 30 per group), particularly in comparison to statin trials, which typically involve many thousands of patients. Also, the experience with fish oil (omega-3 fatty acids) has shown more dramatic survival benefit than with statins in several trials, despite very modest changes in lipoprotein profiles. Given the earlier research with policosanol suggesting many mechanisms of action, it would seem premature to halt research with this agent after several small, negative clinical trials.

NUTRIENT-DRUG INTERACTIONS

Acetylsalicylic Acid (Aspirin) and Other Antiplatelet Medications

Antiplatelet Thromboprophylactics: Acetylsalicylic acid (acetosal, acetyl salicylic acid, ASA, salicylsalicylic acid; Arthritis Foundation Pain Reliever, Ascriptin, Aspergum, Asprimox, Bayer Aspirin, Bayer Buffered Aspirin, Bayer Low Adult Strength, Bufferin, Buffex, Cama Arthritis Pain Reliever, Easprin, Ecotrin, Ecotrin Low Adult Strength, Empirin, Extra Strength Adprin-B, Extra Strength Bayer Enteric 500 Aspirin, Extra Strength Bayer Plus, Halfprin 81, Heartline, Regular Strength Bayer Enteric 500 Aspirin, St. Joseph Adult Chewable Aspirin, ZORprin); combination drugs: ASA and caffeine (Anacin); ASA, caffeine, and propoxyphene (Darvon Compound); ASA and carisoprodol (Soma Compound); ASA, codeine, and carisoprodol (Soma Compound with Codeine); ASA and codeine (Empirin with Codeine); ASA, codeine, butalbital, and caffeine (Fiorinal); cilostazol (Pletal), clopidogrel (Plavix), dipyridamole (Permole, Persantine), ticlopidine (Ticlid); combination drug: ASA and extended-release dipyridamole (Aggrenox, Asasantin).

Monoclonal Antibody Antiplatelet Agents: Abciximab (ReoPro), eptifibatide (Integrelin), tirofiban (Aggrastat).

Blood Viscosity Reducer Agent: Pentoxifylline (Pentoxil, Trental).

Interaction Type and Significance

✗✗ **Minimal to Mild Adverse Interaction—Vigilance Necessary**

⊕✗ **Bimodal or Variable Interaction, with Professional Management**

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **5. Improbable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

In high doses, policosanol can alter prostaglandin synthesis, lower platelet aggregation induced by AA, and inhibit proaggregatory TXA_2 generation induced by collagen.[12-14] Concomitant use of policosanol and antiplatelet medications such as aspirin may produce an additive interaction that, if clinically significant, could be beneficial or potentially detrimental, depending on the clinical circumstances (i.e., whether there is risk of clotting or bleeding).

Research

Arruzazabala et al.[15] conducted a randomized, double-blind, placebo-controlled study involving 43 healthy volunteers to compare the effects of policosanol, aspirin, and combination therapy on platelet aggregation. They found that policosanol alone significantly reduced platelet aggregation induced by adenosine diphosphate (ADP) (37.3%), epinephrine (32.6%), and collagen (40.5%), whereas aspirin alone significantly reduced platelet aggregation induced by collagen (61.4%) and epinephrine (21.9%) but not ADP-induced aggregation. Combined administration of the two agents significantly inhibited aggregation induced by all the agonists, reaching the highest reductions of platelet aggregation induced by collagen (71.3%) and epinephrine (57.5%). Coagulation time did not change significantly in any group. The researchers concluded that policosanol (20 mg/day) is as effective as aspirin (100 mg/day) on platelet aggregation and that combination therapy provided further activity compared with the respective monotherapies.

In a 2-week, randomized, double-blind, placebo-controlled trial involving healthy volunteers, Carbajal et al.[14] observed significant reductions of AA and collagen-induced platelet aggregation in vitro. Furthermore, policosanol also inhibited thromboxane, but not prostacyclin, generation induced by collagen. Likewise, clinical trials investigating the therapeutic effects of policosanol in the treatment of intermittent claudication have consistently demonstrated the agent's antiplatelet activity, with statistically significant improvement in walking distance before onset of pain.[16] In subsequent research involving healthy volunteers and hypercholesterolemic patients, Arruzazabala et al.[17] found that antiplatelet effects resulting

from 40 mg/day policosanol versus 20 mg/day policosanol were similar after 30 days.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The effects of policosanol on platelet aggregation may alter the effects of aspirin and other antiplatelet medications when used concomitantly; modification of therapeutic dose may be necessary. Further research into these potential interactions, their clinical significance, occurrence, and management is warranted. Caution regarding coadministration is advised pending the emergence of such knowledge. Regular monitoring and appropriate titration is recommended. As with aspirin and other agents that inhibit platelet function, patients taking policosanol should be counseled to discontinue it 1 week before elective surgery. In emergency surgery with uncontrolled bleeding where pressure cannot be applied, such as intraspinal or intracranial bleeding, platelet transfusions should be considered in patients who have been taking antiplatelet agents, which may include policosanol.

Anticoagulant Medications

Oral Vitamin K Antagonist Anticoagulants: Anisindione (Miradon), dicumarol, ethyl biscoumacetate (Tromexan), nicoumalone (acenocoumarol; Acitrom, Sintrom), phenindione (Dindevan), phenprocoumon (Jarsin, Marcumar), warfarin (Coumadin, Marevan, Warfilone).
Heparin, Unfractionated (UFH): Heparin (Calciparine, Hepalean, Heparin Leo, Minihep Calcium, Minihep, Monoparin Calcium, Monoparin, Multiparin, Pump-Hep, Unihep, Uniparin Calcium, Uniparin Forte).
Heparinoids: Danaparoid (Orgaran), fondaparinux (Arixtra).
Low-Molecular-Weight (LMW) Heparin: Ardeparin (Normiflo), certoparin (Mono-Embolex), dalteparin (Fragmin), enoxaparin (Clexane, Lovenox), nadroparin (Fraxiparine), tinzaparin (Innohep).
Direct Thrombin Inhibitors: Argatroban, bivalirudin (Angiomax), dabigatran etexilate (Rendix, investigational), desirudin (Iprivask, Revasc), hirudin, lepirudin (Refludan).

Interaction Type and Significance

- ⊕ **Potential or Theoretical Beneficial or Supportive Interaction, with Professional Management**

Probability: **5. Improbable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

In high doses, policosanol can alter prostaglandin synthesis, lower platelet aggregation induced by AA, and inhibit proaggregatory TXA_2 generation induced by collagen.[12-14] Some speculate whether the concurrent use of anticoagulant medications and policosanol might result in an additive effect. In the event that such interaction unintentionally produced unforeseen synergy or were not properly monitored and managed, excessive anticoagulant activity might result in adverse effects, such as excessive hemorrhage or inappropriate blood thinning. Conversely, if clinically significant, intentional coadministration might be efficacious and advantageous.

Research

Several clinical trials have demonstrated that policosanol can significantly inhibit platelet aggregation in humans without affecting coagulation parameters.[13,14,18] Carbajal et al.[19] specifically investigated the effect of concomitant administration of warfarin and single or repeated doses of orally administered policosanol on bleeding time and experimentally induced venous thrombosis in rats. Policosanol alone did not significantly affect fibrinolytic activity or change the bleeding time. Either policosanol or warfarin monotherapy produced a significant reduction of thrombus weight. However, although the combination of policosanol and warfarin induced a moderate but significant prolongation of the bleeding time, this addition of policosanol to warfarin therapy did not enhance the prolongation of the bleeding time induced by warfarin alone. Further, when the combination was used instead of either agent alone, no significant benefits were observed on the reduction of thrombus weight. These findings indicate that any interaction between policosanol and warfarin (or similar agents [e.g., heparin]) is unlikely to be clinically significant.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Caution and regular monitoring remain appropriate, even though available evidence strongly suggests that any potential interaction between policosanol and common anticoagulant medications is unlikely to produce clinically significant adverse effects. It should be noted, however, that any agent with antiplatelet effects, including drugs (e.g., aspirin, Plavix, Persantine), botanicals (e.g., ginkgo, ginger, garlic), or policosanol, can increase the risk of bleeding in anticoagulated patients because both the major hemostatic pathways (platelets and coagulation cascade) are inhibited to some degree. Continued research into policosanol's mechanisms of action and therapeutic effects, along with observation deriving from its wider use, will provide opportunities to assess further the clinical significance (adverse or beneficial) of any interactions between policosanol and warfarin, heparin, or related anticoagulant agents and the frequency of any such events.

Beta-1-Adrenoceptor Antagonists (Beta-1-Adrenergic Blocking Agents) and Related Antihypertensive Medications

Oral forms (systemic).
Evidence: Propranolol (Inderal).
Extrapolated, based on similar properties: Acebutolol (Sectral), atenolol (Tenormin); combination drugs: atenolol and chlortalidone (Co-Tendione, Tenoretic); atenolol and nifedipine (Beta-Adalat, Tenif); betaxolol (Kerlone), bisoprolol (Zebeta), carteolol (Cartrol), esmolol (Brevibloc), labetalol (Normodyne, Trandate), metoprolol (Lopressor, Toprol XL); combination drug: metoprolol and hydrochlorothiazide (Lopressor HCT); nadolol (Corgard), nebivolol (Nebilet), oxprenolol (Trasicor), penbutolol (Levatol), pindolol (Visken), propranolol (Betachron, Inderal LA, Innopran XL, Inderal); combination drug: propranolol and bendrofluazide (Inderex); sotalol (Betapace, Betapace AF, Sorine), timolol (Blocadren).

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

Preliminary research, involving animals but also consistent with known mechanisms of action of policosanol and its constituents, suggests that the effects of policosanol on blood pressure may create additive hypotensive effects when combined with antihypertension medications such as beta blockers.

Research

Molina Cuevas et al.[20] investigated the effect of policosanol on arterial blood pressure in rats and its pharmacological interaction with propranolol and nifedipine (a calcium channel blocker). First, they observed that single doses of policosanol, at various potencies, orally administered to spontaneously hypertensive rats did not significantly change arterial pressure. After administering high doses of policosanol (200 mg/kg) to the rats followed by both antihypertensive agents, they found that such pretreatment with policosanol significantly increased propranolol-induced hypotensive effects without modifying cardiac frequency. No alterations were observed in the effects of nifedipine.

In a 3-year randomized trial, Castano et al.[21] investigated the concomitant use of policosanol and beta blockers in 205 "older hypercholesterolemic patients taking beta-blockers." After a 5-week diet-only baseline period, subjects were randomized to policosanol (5 mg/day) or placebo. After 1 year, subjects receiving policosanol exhibited significantly reduced LDL-C (20.9%), total cholesterol (TC) (19.3%), and triglycerides (TG) (25.7%), along with increased HDL-C levels (4.1%); these beneficial "effects did not wear off" during the 3-year follow-up. After the 3-year trial period, the authors reported that policosanol lowered LDL-C (34.3%), TC (23.2%), and TG (21.2%) and elevated HDL-C (12.3%), and that "reductions in systolic and diastolic blood pressure were observed in policosanol patients compared with those in the placebo group." Notably, of the 31 patients (15.1%) who discontinued the study, 20 (16 in placebo group and 4 in policosanol group) withdrew because of adverse effects. "The frequency of serious adverse events (SAE), mostly vascular," in policosanol patients (3.1%) was lower than in the placebo group (14.0%), with the frequency of policosanol patients reporting mild or moderate adverse effects (18.4%) also lower than in the placebo group (28.0%). The investigators concluded that "policosanol was well tolerated in elderly patients taking beta-blockers," and that additional "reduction of blood pressure and a lower frequency of SAE were observed in policosanol patients compared with those taking placebo." They added that "cholesterol-lowering efficacy of policosanol" was as "expected" and recommended the coadministration of policosanol in "hypercholesterolemic elderly individuals taking beta-blockers could provide additional benefits in lowering blood pressure."[21]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The apparent synergistic interaction observed between policosanol and beta blockers could produce unintended and potentially adverse effects or may be therapeutically efficacious, depending on therapeutic strategy, monitoring, respective dosage titration, and the particular needs and characteristics of the individual patient. Further research involving well-designed clinical trials is warranted to elucidate the potential risks and benefits of this pattern of interaction and enable development of safe and effective guidelines for clinical management. Pending such conclusive research, any concomitant use of policosanol and beta blockers should be approached cautiously, and collaboration between health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics would be judicious and most likely to enhance outcomes.

HMG-CoA Reductase Inhibitors (Statins)

Atorvastatin (Lipitor), fluvastatin (Lescol, Lescol XL), lovastatin (Altocor, Altoprev, Mevacor); combination drug: lovastatin and niacin (Advicor), pravastatin (Pravachol), rosuvastatin (Crestor), simvastatin (Zocor); combination drug: simvastatin and extended-release nicotinic acid (Niaspan).

☐ **Inadequate**

Effect and Mechanism of Action

Given the similar therapeutic objectives and related, if not sequential or redundant, activity and mechanisms of action, an additive or synergistic effect from concomitant use of HMG-CoA reductase inhibitors and policosanol appears possible, but unproven.

Research

Although several studies have compared the therapeutic effects of policosanol and various statin drugs, research is only beginning to emerge investigating the potential for adverse or beneficial effects from coadministration of statin drugs and policosanol.

The authors of the first trial directly investigating such concomitant therapy, however, have expressed a harsh judgment on the effectiveness of such combined treatment and questioned the value of continued research, despite the low dosage, small size, and short duration of their study. In a randomized, parallel, double-blind, double-dummy, placebo-controlled design involving 99 patients with LDL-C levels from 140 to 189 mg/dL, Cubeddu et al.[22] randomized subjects to one of four groups to receive policosanol, atorvastatin, combination therapy, or (double) placebo for 12 weeks. Starting with baseline characteristics that were similar among all treatment groups, the investigators reported that policosanol (20 mg/day) "did not significantly change plasma total cholesterol, LDL-C, high-density lipoprotein cholesterol, or triglyceride levels when compared with baseline values or with values of placebo-treated patients." In contrast, they found that subjects administered atorvastatin (10 mg/day) exhibited "reduced total cholesterol by 27% and LDL-C by 35%." Thus, while noting that policosanol "was safe and did not affect liver enzyme or creatinine phosphokinase levels," they concluded that the addition of "policosanol did not reduce LDL-C or total cholesterol levels either alone or in combination with atorvastatin." Consequently, they recommended that "observation supports the need for systematic evaluation of available products containing policosanol to determine their clinical lipid-lowering efficacy under rigorous experimental conditions." Pending conclusive evidence, they added, "We propose that policosanol should be added to the list of nutritional supplements lacking scientific validity to support their use."[22]

Further research through long-term, well-designed, and adequately powered trials using varying doses and combinations of these agents is warranted.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Unmanaged concurrent use might produce excessive inhibition of cholesterol formation, but adverse events from this hypothetical effect appear improbable. Coordinated use might allow reducing the dosage of the statin and thus moderation of inherent adverse effects on normal liver function. Many nutritionally oriented health care providers already administer policosanol, usually in conjunction with synergistic agents, to phase out and replace statin agents in patients who prefer to avoid the risks known to accompany use of these drugs. Further research involving well-designed clinical trials is warranted to elucidate the potential risks and benefits of this pattern of interaction and enable development of safe and effective guidelines for clinical management.

Pending such conclusive research, any concomitant use of policosanol and statin therapy should be undertaken only under professional supervision and with regular monitoring of lipid levels and liver function. Experienced practitioners of nutritional therapeutics typically combine policosanol and a program of dietary changes and regular exercise with agents such as fish oil, inositol hexaniacinate or time-release niacin, pantethine, and garlic based on the individual patient's particular pattern of dyslipidemia, family history, genomic variables, and other risk factors. Collaboration between health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics would be judicious and most likely to enhance outcomes. Epidemiological investigations have shown an increased risk of hemorrhagic stroke in individuals with very low serum cholesterol levels (< 120 mg/dL).

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Ezetimibe

Ezetimibe (Zetia).

Ezetimibe is a potent and highly specific inhibitor of an intestinal sterol permease. Doses as low as 10 mg/day can suppress intestinal absorption of cholesterol and decrease serum LDL-C by approximately 18%. McCarty[23] hypothesized that coadministration of policosanol and ezetimibe may produce an additive efficacy "that could reduce LDL cholesterol by about 40%, without side effects, and that could be recommended to virtually anyone whose LDL cholesterol levels were not already ideal." Research appears warranted based on trials with each agent individually.

Salicylates

Including: Aspirin, choline salicylate, magnesium salicylate, salsalate, diflunisal, sodium salicylate, sodium thiosalicylate.

Some preliminary research has been interpreted to indicate that effects of policosanol on clotting may alter the effects of salicylates. Even though research findings focusing on policosanol's effects on platelet aggregation and coagulation indicate that adverse effects or interactions are unlikely, any concomitant use of policosanol and salicylates should be undertaken only under close observation and with regular monitoring, until further research provides direct and conclusive evidence of a clinically significant interaction and enables development of guidelines for clinical management of such cases.

See also earlier section on Acetylsalicylic Acid (Aspirin) and Other Antiplatelet Medications.

The 23 citations for this monograph, as well as additional reference literature, are located under Policosanol on the CD at the back of the book.

Probiotics

Nutrient Names: Probiotic intestinal flora and prebiotics.
Synonyms: Healthy bacteria, intestinal microbiota, probiotic flora, symbiotic flora.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Antibiotics Antimicrobials ☼/⊕⊕⊕/◈	Antibiotic agents, particulary repeated courses or high-dose administration, will damage the intestinal flora that are indigenous and intrinsic to the gut ecology and play significant roles in immune, endocrine, detoxification, and other body systems. Repletion of such commensal bacteria and rebuilding of gut ecology through diverse and vigorous probiotic cultures can provide both short- and long-term strategic benefits for preventing or treating many conditions, with minimal risk of adverse effects. Mechanisms and effects established, but controversy exists regarding necessity. Research warranted and ongoing as to particulars and strategies, such as species, strains, dose, and duration.	Administer, especially after high-dose or extended antibiotic therapy; several months may be necessary. *Saccharomyces boulardii* (an antibiotic-resistant probiotic yeast) during or after antibiotic course may also be necessary to counter adverse effects, such as *C. difficile* overgrowth (antibiotic-associated colitis).
Lansoprazole Amoxicillin Metronidazole (LAM) triple therapy ⊕⊕	Coadministration of probiotic flora with triple (or quadruple) therapy can enchance efficacy in eradicating *Helicobacter pylori*. Preliminary supportive evidence; mechanisms partially understood.	Coadminister.

NUTRIENT DESCRIPTION

Chemistry and Forms

Probiotics

Bifidobacterium adolescentis, B. animalis, B. bifidus (bifidum), B. breve, B. infantis, B. lactis, B. longum, B. thermophilum; Lactobacillus acidophilus, L. brevis, L. bulgaricus, L. casei, L. cellobiosus, L. crispatus, L. curvatus, L. fermentum, L., Lactobacillus GG (*L. rhamnosus* or *L. casei* subsp. *rhamnosus*), *L. johnsonii, L. plantarum, L. salivarus; Saccharomyces boulardii, S. cerevisiae.*

Lactobacillus bulgaricus and *Streptococcus thermophilus* are the "yogurt species." *Lactococcus lactis* and *L. lactis* subspecies *cremoris (Streptococcus cremoris)* are also part of milk souring and are used as probiotics.

Enterococcus faecium (also in the streptococcal family) has also been used in the management of diarrheal illness.

Prebiotics

The most common prebiotics are *inulin*, a long-chain oligosaccharide (2-60 sugars), and *fructooligosaccharide* (FOS), a short-chain oligosaccharide (2-7 sugars). Almost all fibers function as prebiotics to some extent, as do many of the sugar alcohols (e.g., lactitol, maltitol, xylitol).

Related Substances

Probiotics: Live-culture foods; kefir, yogurt.
Prebiotics: Artichokes, onions, chicory, garlic, leeks; foods known to contain low-molecular-weight carbohydrates classified as FOS.

Physiology and Function

Probiotics are known by many names, including "live foods," yogurt, lactobacilli, acidophilus, and "cultured" dairy products. The human gastrointestinal (GI) tract is home to more than a trillion live bacteria from about 400 species. The average adult body contains about 20 times more bacteria than it does somatic cells.[1] In the natural environment, a delicate symbiosis evolves between these endogenous bacteria and their host. These live organisms act beneficially by affecting the host animal, improving its intestinal microbial balance. The vital contribution of natural flora to normal intestinal development is underscored by studies of animals raised in a germ-free environment. These animals have hypoplastic intestinal epithelia, reduced gut immunity, and impaired peristalsis, all of which improve only when normal gut flora are introduced.[2] Scientific discoveries continue to highlight the multifaceted functions of intestinal microflora within multiple body systems. For example, emerging research regarding the vermiform appendix suggests that its major physiologic function may be to harbor and protect the commensal colonic flora, so that they are preserved and available to repopulate the colon after severe diarrheal illnesses such as cholera or other types of severe infectious gastroenteritis.[2a]

Probiotics change the metabolic activities or composition of microbiota and modulate immune system reactivity in ways that benefit healthy function. Exogenous probiotics are administered therapeutically to individuals in whom this naturally beneficial symbiosis has been disturbed, in an attempt to restore normal flora. A 2004 Cochrane review reports that probiotic therapy is effective in reducing diarrhea.[3] A 2005 report summarizing 185 studies found that probiotics successfully treated 68 different conditions in diverse populations.[4]

Lactobacillus and *Bifidobacterium* each represent a genus of probiotics most often used therapeutically. Some species and strains are derived from the intestinal microbiota of healthy humans. Some bifidobacteria that have been perpetuated as probiotics for babies have been derived from human milk. Other species are nonhuman probiotics used in the fermentation of dairy products. Species from other bacterial genera, such as *Streptococcus, Bacillus,* and *Enterococcus* have also been used as probiotics, but concerns surround the safety of such probiotics because these genera also contain pathogenic species, particularly *Enterococcus*.[5-9] Nonbacterial microorganisms such as yeasts from the genus *Saccharomyces,* most notably *S. boulardii*, have also been used as probiotics for many years.

Probiotics, as implied by their collective name, are a class of bacteria and yeast that are essentially life supporting in their action within human physiology. Historically, they have always been part of the human digestive tract ecology, with breast-feeding establishing the initial colonization process before the immune system has fully developed the distinction between self and other. Thus, in an immune sense, probiotics are within the boundaries of self in a presumably lifelong symbiotic relationship.

Microflora of the large intestine complete digestion through fermentation, playing a key role in the endogenous synthesis of vitamins (e.g., niacin, folic acid, biotin, K, B_{12}, B_6), short-chain fatty acids, amino acids (e.g., L-arginine, L-cysteine, L-glutamine), and other "gut" nutrients. Microflora protect against overgrowth of opportunistic bacteria and fungi. These layers of tissue facilitate detoxification and stimulate the development of the immune system. For example, the metabolism of food by *Lactobacillus acidophilus* results in the production of lactic acid, hydrogen peroxide, and other beneficial byproducts that support changes in the gut environment hostile to unwanted organisms. Many of these bacteria are able to tolerate environments with a pH of 3 and 2% to 8% concentrations of bile acid. Probiotics in the diet can modify the composition and some metabolic activities of the intestinal microflora.

Certain probiotics are found as the live microorganisms in foods, such as active yogurt culture. Acidophilus organisms can act as a source of lactase. The microorganisms can survive passage through the gut and temporarily bring the benefits of normal gut flora. Bifidobacteria are anaerobic pleomorphic rods or club-shaped organisms that normally have an important role in breaking down dietary carbohydrate and interact directly with the host metabolism. Bifidobacteria also excrete water-soluble vitamins, but species and strains are considerably different. The healthy human gut, without pharmacological disruption, contains a wide range of bacterial species, and once established, variable strains normally grow in number and diversity. Fructooligosaccharides are naturally occurring carbohydrates that support the growth of bifidobacteria and cannot be digested or absorbed by humans.

Pharmacokinetic data suggest that human intestinal flora are essential for hydrolysis of the glycoside forms of the anthocyanin and proanthocyanin moities, as well as the glycoside forms of isoflavones and phytoestrogens.[10-12] These data suggest that iatrogenic reduction in microflora induced by antibiotics may reduce the bioavailability of at least some plant food polyphenols, although clinical evidence is not available.

The ideal probiotic should remain viable at the level of the large intestine and should adhere to the intestinal epithelium to confer a significant health benefit. Viable bacteria have greater immunological effects than nonviable bacteria and killed bacteria have been associated with adverse effects in some cases.[13,14] Some of the best-characterized probiotics have been shown to adhere strongly to intestinal epithelium through in vivo and in vitro studies.[15] Probiotics must also be resistant to gastric acid digestion and to bile salts to reach the intestinal tract intact, and they should be nonpathogenic.[16]

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Probiotics have been clinically used to protect against intestinal permeability resulting from intestinal inflammation induced by nonsteroidal anti-inflammatory drugs (NSAIDs). Probiotics are also used to help reduce the adverse side effect of antibiotic-induced diarrhea. The concern about overuse of antibiotics has recently been noted because of the more frequent overgrowth of antibiotic-resistant bacteria such as *Clostridium difficile*, which causes a severe form of colitis due to antibiotic therapy. Probiotic yeast such as *Saccharomyces boulardii* have been used as specific therapy for *C. difficile* colitis. Probiotics are used to enhance immune system factors to aid in the sequelae of asthma, allergies, upper respiratory infections, eczema, and other autoimmune disorders. Probiotics help replenish the intestinal flora when it is depleted by the factors surrounding infectious diarrhea, irritable bowel syndrome, and other intestinal disorders partly created by a depletion of healthy gut flora.

Historical/Ethnomedicine Precedent

Probiotics in the form of *Streptococcus thermophilus* and *Lactobacillus bulgaricus* in fermented milk have been ingested by humans for thousands of years in the belief they have health benefits. Fermented dairy products such as yogurt have been prepared and consumed since the third millennium BCE, with the earliest uses most likely deriving from experiences of ingesting materials created through spontaneous fermentation by naturally occurring bacteria living on the goatskin bags used by the Bulgars (or Hunno-Bulgars). The development of food derived from fermentation of soy represents a parallel culinary evolution in East Asia. Likewise, in Biblical history, it was written that Abraham owed his fertility and longevity to the regular ingestion of yogurt. In the early twentieth century, the Russian immunologist Elie Metchnikoff proposed that lactic acid bacilli may have beneficial health effects and attributed his own longevity to regular probiotic ingestion.

Possible Uses

Allergic airway disease, allergic reactions (risk reduction and treatment), antibiotic-induced diarrhea, arthritis, atopy (particularly in infants), bone mineralization, calcium absorption, cancer, candidiasis, carcinogenic compound reduction in GI tract, cholesterol, constipation, Crohn's disease, diarrhea, digestive problems, dysbiosis, eczema, enteritis, food intolerances/sensitivities, food poisoning, glutamate synthase, *Helicobacter pylori* infection, hypercholesterolemia, immune enhancement/support, immune system development, intestinal permeability from NSAID-induced intestinal inflammation, irritable bowel disorder, irritable bowel syndrome, lactose intolerance, malnutrition, obesity, oral thrush, osteoporosis, pollen allergy, pouchitis, pseudomembranous colitis, seasonal allergies, sinusitis, surgery recovery, traveler's diarrhea, ulcerative colitis, vaginal infections, vulvovaginitis, workplace wellness (decreased sick leave), yeast infections.

Deficiency Symptoms

The absence of healthy live bacteria in the intestines have led to hypoplastic intestinal epithelia, reduced gut immunity, and impaired peristalsis.[2] The depletion of such organisms tend to increase gut permeability, leaky gut syndrome, dysbiosis, abdominal distention, bloating, abdominal cramping, loose stools, fatigue, constipation, and acute/chronic diarrhea.

Dietary Sources

A wide variety of foods have live bacteria that contain mixtures of lactobacilli and bifidobacteria. These foods include yogurt, kefir, fermented foods such as sauerkraut and kimchi, probiotic foods, and prebiotic foods; most yogurt preparations are usually mixtures of lactobacilli and bifidobacteria, sometimes with

Streptococcus thermophilus. Some "soil organisms" are primarily derived from soil, rather than mammals.

Nutrient Preparations Available

Bifidobacteria, acidophilus, lactobacillus, yogurt, yeasts, fermented foods. Probiotic *Escherichia coli* are available in Germany. The most common prebiotics are inulin and fructooligosaccharides (see Chemistry and Forms).

Dosage Forms Available

Capsule, enema, liquid (oral), liquid (topical); powder.

Most commercially available forms of probiotic supplements are refrigerated until consumption because culture viability remains an important issue in achieving therapeutic effects. Some manufacturers market probiotic products that they claim do not require refrigeration to maintain stability due to freeze-drying or other processes. Nevertheless, shelf life viability of all preparations is somewhat shorter at room temperature than under refrigeration.

Source Material for Nutrient Preparations

Cow's milk, goat milk, human milk; carrots, corn; soil.

Dosage Range

Dosage is represented as number of organisms per dose/serving (often noted as "CFU" for "colony-forming units").

Adult

Dietary: None established.
Supplemental/Maintenance: One capsule or teaspoon per day orally, typically providing 1 to 2 billion CFU.
Pharmacological/Therapeutic: Dosage in clinical trials has ranged from 1 to 20 billion microflora. A typical therapeutic dose of probiotic bacteria is 2 to 4 billion CFU, two to four times daily, and that of *Saccharomyces boulardii* yeast is 500 mg, standardized to provide 3 billion CFU per gram, twice daily. *S. boulardii* is usually administered concurrently with antibiotic therapy, and bacterial probiotics are given after completion of a course of antibiotics, for 1 to 6 months.
Toxic: No toxicity has been established.

Pediatric (< 18 Years)

Dietary: None established.
Supplemental/Maintenance: One capsule or teaspoon per day orally, typically providing 1 to 2 billion CFU.
Pharmacological/Therapeutic: See Adult.
Toxic: None established.

Laboratory Values

Select laboratories have tests for presence, number, types, and characteristics of bacteria, as well as presence of pathogenic microorganisms and excessive gut permeability.

SAFETY PROFILE

Overview

Generally, medical literature reports probiotics as safe for human consumption. Potential benefits must be considered against possible harm, knowing that the data will never be absolute. Relevant data can be divided into two categories: population surveys, both retrospective and prospective, and anecdotal case reports that retrospectively try to establish some connection to prior ingestion of probiotics. Neither category provides a definitive scientific evidence–based overview of the safety of probiotics. Some clinical scientists assert that there will never be definitive clinical data.[17]

Based on Finnish estimates that 0.02% of blood cultures test positive for lactobacilli, more than 166,000 patients would need to be studied prospectively to detect a 10% increase in bacteremia caused by *Lactobacillus*. Even with this estimate, given that blood was cultured in the Finnish study only for clinical indications, the expected yield would likely be lower if blood from healthy patients who ingested probiotics prophylactically were routinely cultured.

Although immunocompromised patients are especially vulnerable to infection, prospective studies have shown that probiotics are safe in immunocompromised adults and children with human immunodeficiency virus (HIV).[18,19]

In preterm neonates, probiotics reduce the incidence and severity of necrotizing enterocolitis, with no secondary probiotic infections seen to date.[20,21]

Sepsis from *Lactobacillus* has not been reported in prospective randomized studies of probiotics. The risk of sepsis from *Lactobacillus* should be weighed against risk of sepsis with more pathological species of bacteria and against risk of the disease that probiotic therapy was meant to prevent.[17] Many *Lactobacillus* species are intrinsically vancomycin resistant but have had a long history of safe use as probiotics. There is no indication thus far that vancomycin-resistant lactobacilli could transfer the resistance to other bacteria by plasmids or other means.[22] Although rare, reports indicating the presence of probiotic bacteria in samples isolated from infected tissues have raised concerns about their intrinsic properties as well as their potential pathogenicity.[23,24] Improperly stored probiotic products may cause nausea and minor GI distress resulting from degradation.

In a paper reviewing safety issues, Hammerman et al.[17] presented anecdotal adverse reports that clinical *Lactobacillus* infections do exist, most often in elderly patients. The most often cited case is a well-qualified report of a 74-year-old woman who developed a liver abscess after ingesting *Lactobacillus rhamnosus* for 4 months. After direct "gram-staining of a hepatic abscess aspirate demonstrated an abundance of polymorphonuclear leukocytes and gram-positive coccobacilli," the authors observed that the "fermentation pattern and enzymatic reactions of this isolate were compatible with a probiotic strain *L. rhamnosus* GG used in dairy products in Finland since 1990."[7] However, they also noted that the "incidence of severe infections caused by lactobacilli is very low." Notably, the case report does not disclose the comedications used by the woman, diagnosed as an adult-onset diabetic, which might reveal the impact of potential adverse effects of any pharmacodynamic interaction occurring with her liver. Another concern would be medications or conditions that might lead to intestinal ulceration, thus providing a portal of entry to the bloodstream for ingested probiotic bacteria. In other case reports, a 67-year-old man with mitral valve regurgitation developed *Lactobacillus* endocarditis and sepsis after a tooth extraction,[8] and a 6-week-old infant developed *Lactobacillus* sepsis, although the child had severe underlying medical problems.[25]

Nutrient Adverse Effects

General Adverse Effects

Mild to moderate flulike symptoms, flatulence, abdominal bloating, nausea, and loose stools, resulting from "die-off"

of pathogenic yeast and bacteria in the gut, are common in the first week of dosing with probiotics, a phenomenon also known as Jarisch-Herxheimer reaction. Temporary dose reduction or temporary cessation and titration of dose and administration interval typically alleviates the discomfort.

Adverse Effects Among Specific Populations

None confirmed.

Pregnancy and Nursing

None established.

Infants and Children

None established. There have been numerous studies illustrating the safety and effectiveness of probiotics with infants.[26-32]

Effect and Mechanism of Action

Probiotics change the metabolic activities or composition of microbiota and modulate immune system reactivity that benefits health. Exogenous probiotics are given therapeutically to individuals in whom this naturally beneficial symbiosis has been disturbed, in an attempt to restore normal flora.

Contraindications

Probiotic agents are potentially contraindicated in immunosuppressed individuals, particularly those with or at risk for ulcerations of the GI tract. Although administration of probiotics is often a core tactic within integrative nutritional therapeutic strategies for immunocompromised patients, a single unqualified case report described an immunosuppressed patient who developed a *Lactobacillus* infection after eating yogurt.[33]

INTERACTIONS REVIEW

Strategic Considerations

Probiotics have been advocated for the prevention and treatment of a wide range of diseases, and strong evidence exists for their efficacy in some clinical scenarios. Probiotics are now widely used in many countries by both consumers and in clinical practice. Given the increasingly widespread use of probiotics, a thorough understanding of their risks and benefits is imperative.

Dietary modulation of gut microbiota with prebiotics and probiotics is an important function in nutritional sciences. In addition, some nutritional approaches use other nutraceuticals and botanicals, such as a modified butyric acid, as well as Chinese herbal formulae and the essential oil of oregano as sequential or symbiotic therapies. *Prebiotics* are defined as a functional food that has nondigestible food ingredients that beneficially affects the host by selectively stimulating the growth and activity of one or a limited number of symbiotic bacteria in the colon. Prebiotics can be nondigestible oligosaccharides and fibers, but also may be poorly absorbed sugars (e.g., D-tagatose) or sugar alcohols (e.g., lactitol, xylitol), which promote the growth of symbiotic colonic microflora. Among the oligosaccharides, inulin and oligofructose have been shown to inhibit growth of pathogens and to display clear bifidogenic properties.[34]

The status of human intestinal ecology radically changed in the past 60 years in a direction far removed from anything comparable to millennia of evolutionary experience. Up until the middle of the twentieth century, the GI tract of adult humans, in both industrialized and undeveloped cultures, was populated by trillions of diverse organisms that might compose 6 to 8 pounds of living mass.[35] However, the status of bacterial microbiota playing their symbiotic role in digestive, immune, and other functions has been significantly altered by the decline of breastfeeding, the introduction of chlorine in water supplies, declining levels of biological activity in agricultural soil, and the massive upsurge in the medical and animal husbandry use of antimicrobial agents, particularly broad-spectrum antibiotics. Subsequently, recognition has grown steadily as to the profound and widespread systemic implications of the depletion of this intimate natural resource within the human ecology and economy. Health care professionals have long recognized the immediate and long-term impact of antibiotic therapy on the intestinal flora, but the pervasive and cumulative, local and systemic sequelae of overgrowth of pathogenic yeast and anaerobic bacteria, with the attendant loss of metabolic activities and buffering presence for the gut mucosa of the symbiotic bacteria, have been more subtle.

Nevertheless, research into the particulars of such adverse effects has been absent or negligible. Scientific experiments and well-designed clinical trials are needed to investigate critical issues such as the variable susceptibilities within patient populations based on perinatal and infant nutrition, the divergent impact of antibiotics versus other medications as well as specific versus broad-spectrum antibiotics, and the differential effects of short-term versus chronic medication regimens and isolated versus repeated antibiotic administration. In addition, high-quality studies are needed regarding the efficacy of intake of cultured foods such as yogurt versus probiotic products on symbiont repletion, and on the effectiveness of various therapeutic repletion tactics, such as flora constituents (e.g., species, strains), methods of gut preparation and role of prebiotics in reestablishing a dynamic symbiotic microbiota, necessary numbers of organisms, combinations and duration of intake, methods of preparation, and methods of stabilization and delivery of probiotic organisms. In many respects, these concerns include the inherently related and increasingly critical issue of antibiotic-resistant pathogens. Moreover, critical investigation is required to determine the degree to which botanical and nutritional agents might also decimate and disrupt, or support and enhance, healthy flora and gut ecology.

Probiotic repletion and rejuvenation of the gut mucosa have long played a central role in the therapeutic strategies of experienced practitioners within nutritional, naturopathic, and integrative medicine. Given the patient population and their typical medical histories, it is often assumed that healthy flora are lacking and that degradation of the gut integrity and ecology has ensued to such a degree as to participate in a general decline in health and an increase in susceptibility because of decreased function and increased toxic load. Thus, in so many cases, whether labeled with such vaguely defined syndromes as "fibromyalgia," "chronic fatigue," or "food sensitivities," or more conventionally as asthma and atopy, irritable bowel, or constipation, the initial stages of treating a patient with chronic conditions centers around improving dietary habits and reconstructing the gut ecology. However, as in so many areas of integrative medicine's maturation, it is necessary to move past naive assumptions that naturally occurring substances are inherently benign and universally beneficial. Such an approach must give way to a scientifically based and clinically efficacious approach employing all agents, regardless of origins, as potential tools in evolving and multidisciplinary strategies personalized to optimal intervention, given individual

pharmacogenomic and biochemical variability and responses to therapeutic interventions.

A cursory review of the scientific literature over the past 20 years reveals a rapidly ascending curve representing the numbers of scientific studies and published papers focusing on the physiology and therapeutics of probiotics, prebiotics, and related topics. For example, there is clinical evidence to show that probiotics may help children with food sensitivities, whereas there was no effect in those without food sensitivities.[36]

Probiotic therapy has been applied for decades, if not millennia, in many clinical circumstances, from treating asthma and irritable bowel syndrome to preventing thrush or constipation. Research into the safety, applicability, and efficacy of probiotics needs to keep pace with their rapidly expanding popularity in the consumer market and their continued expansion within professional medical contexts.

NUTRIENT-DRUG INTERACTIONS

Antibiotics/Antimicrobial Agents (Systemic)

Aminoglycoside Antibiotics: Amikacin (Amikin), gentamicin (G-mycin, Garamycin, Jenamicin), kanamycin (Kantrex), neomycin (Mycifradin, Myciguent, Neo-Fradin, NeoTab, Nivemycin), netilmicin (Netromycin), paromomycin (monomycin; Humatin), streptomycin, tobramycin (AKTob, Nebcin, TOBI, TOBI Solution, TobraDex, Tobrex).

Beta-Lactam Antibiotics: Methicillin (Staphcillin); aztreonam (Azactam injection); carbapenem antibiotics: meropenem (Merrem I.V.); combination drug: imipenem and cilastatin (Primaxin I.M., Primaxin I.V.); penicillin antibiotics: amoxicillin (Amoxicot, Amoxil, Moxilin, Trimox, Wymox); combination drug: amoxicillin and clavulanic acid (Augmentin, Augmentin XR, Clavulin); ampicillin (Amficot, Omnipen, Principen, Totacillin); combination drug: ampicillin and sulbactam (Unisyn); bacampicillin (Spectrobid), carbenicillin (Geocillin), cloxacillin (Cloxapen), dicloxacillin (Dynapen, Dycill), mezlocillin (Mezlin), nafcillin (Unipen), oxacillin (Bactocill), penicillin G (Bicillin C-R, Bicillin L-A, Pfizerpen, Truxcillin), penicillin V (Beepen-VK, Betapen-VK, Ledercillin VK, Pen-Vee K, Robicillin VK, Suspen, Truxcillin VK, V-Cillin K, Veetids), piperacillin (Pipracil); combination drug: piperacillin and tazobactam (Zosyn); ticarcillin (Ticar); combination drug: ticarcillin and clavulanate (Timentin).

Cephalosporin Antibiotics: Cefaclor (Ceclor), cefadroxil (Duricef), cefamandole (Mandol), cefazolin (Ancef, Kefzol), cefdinir (Omnicef), cefepime (Maxipime), cefixime (Suprax), cefoperazone (Cefobid), cefotaxime (Claforan), cefotetan (Cefotan), cefoxitin (Mefoxin), cefpodoxime (Vantin), cefprozil (Cefzil), ceftazidime (Ceptaz, Fortaz, Tazicef, Tazidime), ceftibuten (Cedax), ceftizoxime (Cefizox), ceftriaxone (Rocephin), cefuroxime (Ceftin, Kefurox, Zinacef), cephalexin (Keflex, Keftab), cephapirin (Cefadyl), cephradine (Anspor, Velocef); imipenem combination drug: imipenem and cilastatin (Primaxin I.M., Primaxin I.V.); loracarbef (Lorabid), meropenem (Merrem I.V.).

Fluoroquinolone (4-Quinolone) Antibiotics: Cinoxacin (Cinobac, Pulvules), ciprofloxacin (Ciloxan, Cipro), enoxacin (Penetrex), gatifloxacin (Tequin), levofloxacin (Levaquin), lomefloxacin (Maxaquin), moxifloxacin (Avelox), nalidixic acid (Neggram), norfloxacin (Noroxin), ofloxacin (Floxin, Ocuflox), sparfloxacin (Zagam), trovafloxacin (alatrofloxacin; Trovan).

Macrolide Antibiotics: Azithromycin (Zithromax), clarithromycin (Biaxin), dirithromycin (Dynabac), erythromycin, oral (EES, EryPed, Ery-Tab, PCE Dispertab, Pediazole), troleandomycin (Tao).

Sulfonamide Antibiotics: Sodium sulfacetamide (AK-Sulf, Bleph-10, Sodium Sulamyd), sulfamethoxazole (Gantanol), sulfanilamide (AVC), sulfasalazine (salazosulfapyridine, salicylazosulfapyridine, suphasalazine; Apo-Sulfasalazine, Azulfidine, Azulfidine EN-Tabs, PMS-Sulfasalazine, Salazopyrin, Salazopyrin EN-Tabs, SAS), sulfisoxazole (Gantrisin); combination drug: sulfamethoxazole and trimethoprim (cotrimoxazole, co-trimoxazole, SXT, TMP-SMX, TMP-sulfa; Bactrim, Bactrim DS, Cotrim, Septra, Septra DS, Sulfatrim, Uroplus); triple sulfa (Sultrin Triple Sulfa).

Chemotherapy, Cytotoxic Antibiotics: Bleomycin (Blenoxane), dactinomycin (Actinomycin D, Cosmegen, Cosmegen Lyovac), mitomycin (Mutamycin), plicamycin (Mithracin).

Miscellaneous Antibiotics/Antimicrobials: Bacitracin (Caci-IM), chloramphenicol (Chloromycetin), chlorhexidine (Peridex), clindamycin, oral (Cleocin), colistimethate (Coly-Mycin M), dapsone (DDS, diaminodiphenylsulphone; Aczone Gel, Avlosulfon), furazolidone (Furoxone), lincomycin (Lincocin), linezolid (Zyvox), nitrofurantoin (Macrobid, Macrodantin), trimethoprim (Proloprim, Trimpex), vancomycin (Vancocin).

Effect and Mechanism of Action

Probiotics play a critical role in normal functions of the digestive, immune, endocrine, and other body systems but also inhibit growth of potential pathogenic organisms. The potential pathogens produce indole, skatol, putricine, cadaverine, endo-, exo-, and enterotoxins as well as other pathogenic materials; notably, both pathogenic and probiotic bacteria are capable of producing lactic acid and bacteriocins. The inhibition caused by probiotics is antagonistic to pathogen growth. Probiotics provide a competitive environment that does not favor the growth of enteric pathogens. Probiotics trigger cytokine synthesis from enterocytes by attaching to their surfaces. Probiotics restore the normal intestinal flora after antibiotic therapy and produce metabolites, such as hydrogen peroxide and bacteriocins, that are toxic to many pathogenic bacteria. Probiotics also produce butyric and other short-chain fatty acids that both nourish and increase the turnover of enterocytes. Probiotics are also capable of neutralizing many dietary carcinogens.

Research

Antibiotic resistance of pathogens is at the forefront of medical challenges in both the clinical and the public health arena.

Bacteria have mutated over the last 60 years to become resistant to many antibiotic therapies. Even though antibiotics are an effective tool in the treatment of many serious infections, the spread of resistance genes and resistant bacteria impedes the effectiveness of antibiotics as a clinical tool.[37] The risks potentially associated with antibiotic therapy, as a general rule, are multifaceted. The selection of resistant forms can occur during or after microbial treatment. Antibiotic residues can be found for long periods after treatment. Stuart Levy[37] notes that "there is a mounting use of other agents aimed at destroying bacteria, namely the surface antibacterials now available in many household products." The term "multidrug resistance" (MDR) initially described resistant mammalian tumor cells and later strains of *Mycobacterium tuberculosis;* MDR now describes multidrug resistance in any organism—bacterium, fungus, or parasite.[38-44]

Diarrhea is a common adverse effect of antimicrobial therapy, largely from the elimination of beneficial bacteria normally found in the colon. Controlled studies have shown that coadministration of probiotic microorganisms such as *Lactobacillus casei, L. acidophilus, Bifidobacterium longum,* or *Saccharomyces boulardii* can prevent or resolve antibiotic-induced diarrhea.[45] The diarrhea experienced by many patients after antibiotic therapy is sometimes caused by an overgrowth of the anaerobic bacterium *Clostridium difficile,* which causes a disease known as pseudomembranous colitis. Controlled studies have shown that coadministration of probiotic yeast, specifically *S. boulardii* or *Saccharomyces cerevisiae,* helps prevent recurrence of this infection. In one study, administration of 500 mg *S. boulardii* twice daily enhanced the effectiveness of vancomycin in preventing recurrent *Clostridium* infection.[45,46]

The general literature suggests that two categories define the interactions between uses of probiotics and antibiotics. First, the antibiotics may deplete or interfere with the absorption, viability, or function of the probiotics; theoretically, ingesting these organisms may help replenish them. Second, the probiotic may reduce the likelihood or severity of the potential adverse effects of the antibiotics.

Probiotic therapies can offset the loss of GI flora associated with antibiotic therapy.[47] Probiotic therapy can be fundamental to strategic case management for a wide range of chronic conditions, particularly digestive and immune conditions, within the diverse disciplines of natural medicine, nutritional therapeutics, and integrative care. In persons with suspected or diagnosed yeast/fungal intestinal overgrowth, probiotics are typically administered in conjunction with or following antifungal agents, along with nutrients intended to reduce gut permeability and reestablish integrity and normal function of mucous membranes of the GI tract.

The strongest evidence for the use of probiotics is in the management of diarrheal diseases.[16] A meta-analysis of randomized controlled trials demonstrated that many probiotics are effective in preventing antibiotic-associated diarrhea.[48] The agents cited in this meta-analysis included the yeast strain *Saccharomyces boulardii,* as well as the bacterium *Lactobacillus acidophilus* in combination with *L. bulgaricus, L. rhamnosus* strain GG [American Type Culture Collection (ATCC) 53103;LGG], and *Enterococcus faecium* strain SF68. Separate meta-analysis of randomized controlled trials showed a variety of probiotics, including *Lactobacillus* species, *Enterococcus* species, and *S. boulardii,* to be efficacious with infective diarrhea in both children and adults.[16] Probiotics were found to reduce the duration of diarrhea by more than 30 hours. Efficacy in this setting is also supported by a randomized clinical trial of a probiotics mix. The mix included 3×10^{11} CFU *L. bulgaricus, L. casei, L. plantarum, L. acidophilus, Bifidobacterium longum, B. breve, B. infantis,* and *Streptococcus thermophilus.*

A different probiotic mix, *Bifidobacterium lactis* Bb12 and *Lactobacillus reuteri* (ATCC55730) at 1×10^7 CFU, has been shown to be useful in preventing flares of chronic pouchitis in patients with inflammatory bowel disease and diarrheal illness in infants attending child care.[49,50] (*Pouchitis* refers to inflammation of the rectal stump in patients who are status/post–colectomy with ileostomy.) The use of probiotic species, including *B. longum, L. acidophilus, L. casei, S. boulardii,* and *Saccharomyces cerevisiae,* provide a reduction and prevention of the potential adverse effect of diarrhea with antibiotics.[3,45,46,51-55]

The scientific literature provides only minimal evidence from laboratory experiments and clinical trials investigating the differential impact of various antibiotic agents and classes on particular native species and strains of gut flora or the preventive or therapeutic application of probiotics in conjunction with or after particular antibiotics. However, the primary focus of scientific research and clinical administration of probiotic therapy continues to center on *Bifidobacterium longum, Lactobacillus acidophilus, Lactobacillus casei, Saccharomyces boulardii,* and *Saccharomyces cerevisiae,* which can prevent or reduce the severity of diarrhea, a significant and often serious potential adverse effect.[3,45,46,51-54] *S. boulardii* provides a supportive interaction that may support and enhance the therapeutic activity of the concomitant antibiotic.[55,56] In addition, *L. acidophilus* GG enables the recolonization of human colonic mucosa and enhances the therapeutic efficacy of the antibiotic agent.[18,57-59]

Important examples of clinical applications for probiotic therapy are discussed next.

Antibiotic-Induced Diarrhea. Many studies have examined probiotic therapy in the prevention of antibiotic-associated diarrhea. A study of patients receiving extensive antibiotic treatment indicates that 2 years of probiotic therapy (at 2×10^{10} CFU daily) provided a protective strategy for reestablishing healthy flora in these patients.[55]

Atopic Dermatitis and Food Sensitivity. The use of probiotic therapy as part of treatment for atopic dermatitis is well documented and is often considered most efficacious in treating patients with food sensitivities who are also affected by atopic dermatitis.[36]

Clostridium difficile Pseudomembranous Colitis. The higher risk of serious GI diseases caused by antibiotic therapy makes probiotics a unique protective and therapeutic agent. *Clostridium difficile* infection is usually curable but can be very debilitating, especially in elderly or seriously ill patients. It also recurs repeatedly in some patients and occasionally causes life-threatening inflammation of the colon. This strain presents a growing challenge across North America and Europe. A virulent, once-rare strain has driven a string of recent outbreaks and is suspected to be responsible for much of the overall increase in the disease. New resistance to widely used antibiotics seems to have made the microbe more likely to cause diarrhea in sick and elderly people. At the same time, researchers are concerned about scattered cases of *C. difficile* among people not normally susceptible to the organism. In the United States, "the rate of C-diff in hospital patients doubled between 2000 and 2003," reports McDonald et al.[60] of the Centers for Disease Control and Prevention (CDC) in Atlanta. *Saccharomyces boulardii* has been successfully used in treatment of *C. difficile* colitis, usually after failure of metronidazole and

oral vancomycin.[45] Anecdotal clinical experience suggests that prophylactic use of 9 to 10 billion CFU daily of *S. boulardii* concomitantly with broad-spectrum antibiotics may prevent overgrowth of *C. difficile*. Adequately powered, randomized clinical trials of this strategy would appear justified in view of this growing problem among hospitalized patients.

Enteric Colonization of Candida in Neonatal Patients. Oral coadministration of *Lactobacillus casei* subspecies *rhamnosus* (LGG) reduces the incidence and intensity of enteric colonization by *Candida* species in very-low-birth-weight neonates. The ability of LGG to prevent colonization by fungi might translate into a similar ability to prevent fungal infections. In a randomized trial involving 80 preterm neonates, Manzoni et al.[61] administered LGG (6×10^9 CFU/day), delivered in human milk and compared to human milk alone, for 6 weeks until discharge from the neonatal intensive care unit. They observed that the incidence of fungal enteric colonization was significantly lower in the LGG group than in the control group (23.1% vs. 48.8%). Furthermore, the number of fungal isolates obtained from each neonate and each colonized neonate was also significantly lower in the LGG group. Overall, the reduction in GI colonization reached significance in neonates with a birth weight of 1001 to 1500 g, but was not significant in those with a lower birth weight. LGG was not isolated from blood cultures or other specimens, and there were no adverse effects.

Inflammatory Bowel Disease. Probiotics, prebiotics, and antibiotics can provide significant benefit to patients with inflammatory bowel disease (IBD). Probiotics and prebiotics are the type of therapy that appeals to most patients with IBD. Probiotics have no significant adverse effects, except possibly a transient increase in abdominal gas with prebiotics, and thus far appear to be entirely safe. More than a dozen studies using probiotics in IBD indicate clear benefit in pouchitis and possibly in Crohn's disease. Further clinical trials are warranted investigating treatment of ulcerative colitis. The use of oligosaccharide and other prebiotics within conventional therapy for IBD is in its infancy, although significant effects on both the luminal and the mucosa-associated flora have been demonstrated in healthy subjects. Probiotics and prebiotics could play a central role in standard treatment of patients with IBD, although these therapies carry an uncertain risk of potential adverse effects. Their efficacy in clinical studies varies, with Crohn's disease and pouchitis reporting more benefit than ulcerative colitis. However, the ideal combination of conventional interventions, probiotics, and prebiotics and criteria for their application has not been determined.[62]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians can prevent and treat a wide range of disorders and support restoration of healthy physiological function by instituting a strategy built around probiotic repletion. Survey data and anecdotal experience strongly indicate that probiotics, usually in combination with prebiotics and other supportive measures, are often self-prescribed by individuals during or after antibiotic therapy.

Common therapeutic applications of probiotics include improving general gut health; improving the body's natural defenses; reversing patterns of fungal overgrowth, deteriorated intestinal function, and immune compromise; and reducing blood cholesterol levels. The American College of Nutrition recommends, in its nutrition specialist certification review materials, that 6 months of probiotic therapy, with at least 10 billion probiotic organisms daily, is usually indicated to reverse the effects of antibiotic therapy and reestablish healthy gut microbiota.

Helicobacter pylori Triple Therapy (LAM)/Quadruple Therapy

Lansoprazole-amoxicillin-metronidazole (LAM) triple-therapy regimen: Lansoprazole (Prevacid), amoxicillin (Amoxil, Polymox, Trimox, Wymox; Augmentin), metronidazole (Flagyl, Protostat).

Related: HeliMet (Wyeth; discontinued August 2005 in United Kingdom): Lansoprazole (Zoton), clarithromycin (Klaricid), metronidazole.

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability:	Evidence Base:
2. Probable	◉ **Emerging**

Effect and Mechanism of Action

Probiotics can be incorporated into a triple-therapy (or quadruple-therapy) methodology using a proton pump inhibitor (PPI) and two antibiotics.[47,63] Higher eradication rates are found with the coadministration of probiotic agents and pharmaceutical agents.

Research

In a trial involving 138 patients in whom triple therapy failed, Sheu et al.[47] found that a 4-week pretreatment with *Lactobacillus*- and *Bifidobacterium*-containing yogurt (AB-yogurt) "can decrease *H. pylori* loads despite antimicrobial resistance, thus improving the efficacy of quadruple therapy in eradicating residual *H. pylori*."

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing triple (or quadruple) therapy for recalcitrant *Helicobacter pylori* infection are advised to consider coadministration of probiotic flora during and after such eradication therapy.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Sulfasalazine

Sulfazalzine (Salazosulfapyridine, salicylazosulfapyridine, suphasalazine; Apo-Sulfasalazine, Azulfidine, Azulfidine EN-Tabs, PMS-Sulfasalazine, Salazopyrin, Salazopyrin EN-Tabs, SAS).

Findings from an in vitro experiment suggest that *Lactobacillus acidophilus* may accelerate metabolism of sulfasalazine. The occurrence of this pharmacodynamic phenomenon has not been established in humans, nor has any pattern of clinical significance emerged. The authors studied bacterial metabolism of three drugs (sulfasalazine, phthalylsulfathiazole, and chloramphenicol palmitate) and two dyes (tartrazine and methyl red) using a resting culture technique. The strains used were isolated intestinal lactobacilli, *E. coli*, and mixed cultures of feces of mice. One strain of *L. acidophilus* exhibited degradation of sulfasalazine as high as 94.3%. In contrast, the highest degradation of phthalylsulfathiazole and chloramphenicol palmitate was found to be 17.6% and 8%, respectively. The authors also discussed toxicological aspects of degradation products in relation to the use of lactobacilli as dietary supplement or therapeutic aid.[64] Although highly preliminary, these data suggest that although probiotics may

potentially have beneficial effects in inflammatory bowel disease, at least certain strains might increase the metabolism of sulfasalazine with coadministration. If unexpected relapse of symptoms were to occur in IBD patients taking both sulfasalzine and probiotics, consideration should be given to discontinuing probiotics and/or increasing the dose of sulfasalazine.

NUTRIENT-NUTRIENT INTERACTIONS

Oligosaccharides and Other Prebiotics

Health care professionals trained and experienced in nutritional therapeutics and integrative care strategies often use prebiotic therapy to "fertilize" the gut before probiotic therapy and thereby enhance its effectiveness. For example, using a murine influenza vaccination model examining a specific prebiotic-oligosaccharide mixture, with stimulation of delayed-type hypersensitivity, Vos et al.[65] suggest that application use of galactooligosaccharides (GOS) and fructooligosaccharides (FOS) in dietary products might provide an opportunity to stimulate the adaptive immune response in a direction favoring T-helper cell type 1 (Th1) immunity and subsequently inhibit infections and T-helper 2 (Th2)–related immune disorders (e.g., allergic/atopic disease) in humans.[65]

Oligosaccharides in breast milk or added to infant formula modulate postnatal immune development by altering bowel flora and have a potential role in primary allergy prevention during infancy. Infant formulas enhanced with prebiotic oligosaccharides were found to modify intestinal bacteria and more than halve the risk of atopic dermatitis among high-risk babies. In a 6-month, double-blind, randomized, placebo-controlled trial of 259 infants at risk for atopy, only 10 of 102 infants given prebiotics in their formula developed atopic dermatitis, according to an online report in the July 2006 *Archives of Disease in Childhood*. By contrast, 24 of 104 controls given formula without probiotics developed the disorder.[66]

The effect of oligofructose (OF, prebiotic) on microflora in infants is being increasingly studied. A double-blind placebo-controlled trial assessed the effect of daily OF administration on the intestinal microflora, intestinal tolerance, and well-being of healthy infants age 7 to 19 months, with 8 days of observation, 21 days of administration, and 15 days of post-treatment. Exclusion criteria included antibiotic use and intake of another prebiotic or probiotic any time after enrollment. Fecal flora were analyzed by culture methods, and health information was recorded daily. Bifidobacteria tended to increase slightly with OF administration, but not with placebo. Simultaneously, a decrease in potential pathogens, significant for clostridia but not for staphylococci, was observed in the OF group. These modifications did not persist during the post-treatment period. OF intake was accompanied by less flatulence, diarrhea, vomiting, and fever events.[34]

Administration of probiotics and prebiotics can reduce incidence of eczema in infants. Eczema, also known as atopic dermatitis (AD), is one of the first signs of allergy during the early days of life and is believed to result from delayed development of the immune system. According to the American Academy of Dermatologists, eczema affects 10% to 20% of all infants, but almost half will "grow out" of eczema between ages 5 and 15. The research adds to a 2003 study from Finland that reported children exposed to the *Lactobacillus rhamnosus* GG (LGG) bacteria around birth were 40% less likely to develop AD at 4 years of age compared with children in a placebo group. In the new study (2006), Kukkonen et al.[67] from the University of Helsinki built on these earlier results by examining the effects of a probiotic and prebiotic combination on allergy prevention in a much larger population of allergy-prone infants than previously studied. The researchers randomized 1223 pregnant women to receive either placebo or daily probiotic formulation containing four probiotic strains: *Lactobacillus rhamnosus* GG, *L. rhamnosus* LC705, *Bifidobacterium breve* Bb99, and *Propionibacterium freudenreichii* ssp. *shermanii* JS. The women were treated for the 2 to 4 weeks before delivery. The newborns then received either the same probiotics in combination with GOS (461 babies) or placebo (464 babies) for 6 months. Researchers have found that breast milk naturally contains prebiotic oligosaccharides, believed to stimulate bifidobacteria that facilitate the release of energy and nutrients from the diet. No significant differences were observed between the treated and placebo groups with regard to allergic disease overall, but the researchers reported that administration of the probiotic/prebiotic mixture was associated with a 26% reduction in eczema and a 34% reduction in atopic eczema specifically. Fecal samples revealed that the probiotic/prebiotic group had significantly higher lactobacilli, propionibacteria, and bifidobacteria populations. This result indicated "successful intervention and good adherence." According to the researchers:

> Our prospective study indicates, for the first time to our knowledge, an inverse association between the prevalence of eczema and the abundance of certain species of the indigenous gut microbiota, thus supporting the important role of commensal bacteria in the pathogenesis of eczema.... Gut microbiota contact directly with extensions of dendritic cells, which orchestrate the mucosal immune homeostasis. Commensal bacteria stimulate the innate immune system and contribute to the generation of regulatory lymphocytes, which, through IL-10 and TGF-beta, establish and maintain mucosal immune tolerance.[67]

The results show that probiotics and prebiotics offer an "easily accessible, inexpensive, and safe" way of reducing eczema in infants, particularly high-risk infants. The researchers said that continued follow-up on these same infants will show if this effect is maintained later in life, and if any impact on airway allergies such as asthma is observed.[67]

Milk formulas containing prebiotics help floral inoculation with beneficial bacteria. Antibiotics exert deleterious effects on the intestinal microbiota, favoring the emergence of opportunistic bacteria, pathogenic yeasts, other fungi, and diarrhea. Prebiotics are nondigestible food components that stimulate the growth of bifidobacteria and other symbionts. To study the effects of probiotic administration after antibiotic treatment, Brunser et al.[68] conducted a randomized, double-blind, controlled clinical trial involving 140 infants 1 to 2 years of age distributed into two groups after being treated for acute bronchitis with a 1-week course of amoxicillin (50 mg/kg/day). For 3 weeks the children received greater than 500 mL/day of a prebiotic formula (4.5 g/L) or placebo. Fecal samples obtained at the beginning of the antibiotic treatment ("day seven"), at the end of the treatment and before formula administration ("day zero"), and during formula administration ("days seven and twenty-one") were evaluated for *Bifidobacterium, Lactobacillus-Enterococcus, Clostridium lituseburiense* cluster, *Clostridium histolyticum* cluster, *Escherichia coli,* and *Bacteroides-Prevotella*. The authors reported that amoxicillin decreased total fecal bacteria and increased *E. coli*, whereas the prebiotic group exhibited significantly increased bifidobacteria, from 8.17 ± 1.46 on day zero to 8.54 ± 1.20 on day seven, compared with the control 8.22 ± 1.24 on day

zero versus 7.95 ± 1.54 on day seven. The *Lactobacillus* population showed a similar tendency, but the other bacteria were unaffected. Adverse GI symptoms were absent during the prebiotic administration. The authors concluded that prebiotics "in a milk formula increase fecal bifidobacteria early after amoxicillin treatment without inducing gastrointestinal symptoms."[68] Continued research is warranted to investigate further the synergistic use of prebiotics and probiotics directly after antibiotic therapy or in response to long-term sequelae associated with, or aggravated by, the adverse effects of antibiotic therapy.

Prebiotics and calcium exhibit a synergistic relationship in the process of bone mineralization. In a randomized, placebo-controlled trial, Abrams et al.[69] found that a combination of prebiotic short-chain and long-chain inulin-type fructans enhances calcium absorption and long-term bone mineralization in young adolescents. The investigators randomly assigned pubertal adolescents to receive 8 g/day of a mixed short and long degree of polymerization, inulin-type fructan product (fructan group) or maltodextrin placebo (as control). At baseline and after 1 year, they measured bone mineral content, bone mineral density, and calcium absorption; they also determined polymorphisms of the Fok1 vitamin D receptor gene. Subsequently, they observed that after both 8 weeks and 1 year, calcium absorption was significantly greater in the fructan group than in the control group. Notably, an "interaction with Fok1 genotype was present such that subjects with an ff genotype had the least initial response to fructan." After 1 year, the "fructan group had a greater increment in both whole-body bone mineral content ... and whole-body bone mineral density ... than did the control group." The authors concluded that daily "consumption of a combination of prebiotic short- and long-chain inulin-type fructans significantly increases calcium absorption and enhances bone mineralization during pubertal growth." They also added that effects of "dietary factors on calcium absorption may be modulated by genetic factors, including specific vitamin D receptor gene polymorphisms."[69]

These findings indicate that further research investigating this synergistic intervention is warranted (preferably with calcium, vitamin D, and magnesium administration controlled), especially given the critical importance of establishing maximal bone density during adolescence and early adulthood. Similar study of the potential impact of prebiotic nutritional support in adults of different age groups, particularly perimenopausal and postmenopausal women, also appears highly relevant.

HERB-NUTRIENT INTERACTIONS

Numerous botanical agents from European, American, and Asian traditions of herbal medicine appear to require the action of intestinal bacteria to attain their biologically active form (e.g., see Licorice monograph). Research is lacking on the effect of loss of gut bacteria on clinical efficacy of these traditional therapeutic interventions, but the implications could be profound not only for the indigenous populations employing these classical methods of healing in their native context, but also for researchers attempting to validate their effects in an average "Western" (i.e., modern) patient population who have presumably been treated with numerous courses of antibiotics, but not with subsequent, thorough probiotic repletion.

Echinacea

Echinacea *(Echinacea angustifolia, Echinacea purpurea)*.

In a 10-day randomized trial involving 15 healthy adults, Hill, Foote, et al.[70] observed potentially problematic changes in intestinal microbiota after *Echinacea* administration. The investigators reported that standardized *E. purpurea* (1000 mg daily) stimulated the growth of certain *Bacteroides* species of intestinal bacteria, which may act as pathogens, particularly when the gut ecology has been disrupted. In stool samples they found *Echinacea* use associated with increased counts for three groups of organisms: the total group of aerobic bacteria, the anaerobic *Bacteroidet* in general, and *Bacteroides fragilis* in particular. The authors concluded that the "health consequences associated with this change are unknown." Notably, reports of potentially related adverse events associated with echinacea use, such as irritable bowel syndrome or other pathological responses that might be predicted to result from such unfavorable alterations, are lacking.

Although similar findings for echinacea or other herbs (e.g., goldenseal, isatis) often used as antimicrobial/immunostimulant agents are generally absent in the scientific literature, such effects from chronic unsupervised use at high doses would not necessarily be unexpected. Further research and judicious pharmacovigilance are appropriate and necessary as the use of botanical medicine grows within the consumer self-care market and professional therapeutic application.

Ginseng, Chinese/Korean

Chinese/Korean ginseg *(Panax ginseng)*.

Ginseng interacts as a proactive factor with intestinal bacteria. It is activated in the body by intestinal bacterial deglycosylation. Orally ingested ginsenoside passes through the stomach and small intestine, without decomposition by either gastric juice or liver enzymes, into the large intestine, where ginsenoside is deglycosylated by colonic bacteria, followed by transit to the circulation. Colonic bacteria cleave the oligosaccharide connected to the aglycone stepwise from the terminal sugar to afford the major metabolites, 20S-protopanaxadiol 20-O-beta-D-glucopyranoside (M1) and 20S-protopanaxatriol (M4). These metabolites are further esterified with fatty acids, and the resultant fatty acid conjugates are sustained in their active state in the body longer than parental metabolites. Growing evidence indicates that ginsenoside is a prodrug that is activated in the human body by intestinal bacterial deglycosylation and fatty acid esterification.[71] Research investigating the potential decreased efficacy of treatment with ginseng preparation in individuals with diminished intestinal flora, and possible enhancement of effect with restoration of gut ecology through probiotic repletion, represents a promising direction for creative endeavor in integrative medical approaches.

The 72 citations for this monograph, as well as additional reference literature, are located under Probiotics on the CD at the back of the book.

S-Adenosylmethionine (SAMe)

Nutrient Name: S-adenosylmethionine (SAMe).
Synonyms: S-adenosyl-L-methionine, S-adenosyl methionine, ademetionine; AdoMet.

Summary

Drug/Class Interaction Type	Mechanism and Significance	Management
Acetaminophen ☼	SAMe reduces acetaminophen hepatotoxicity. Further research warranted to confirm efficacy and establish dosage and treatment guidelines.	May be effective with or in place of NAC as an antidote in treatment of acetaminophen toxicity.
Imipramine Tricyclic antidepressants (TCAs) ⊕⊕/⊕✗/✗✗	SAMe can accelerate onset of action of imipramine. Concomitant administration could be therapeutic with proper management. Additive or synergistic effect may theoretically result from concomitant use of SAMe and TCAs because of their potentially similar influences on CNS.	Coadministration may be beneficial. May need to modify drug dosage. Monitor and titrate.
Levodopa Antiparkinsonian medications ✗/◈◈/⊕✗/⊕	SAMe tends to be low in Parkinson's disease and levodopa therapy depletes the body of SAMe. However, SAMe may contribute to Parkinson-like motor impairments and interfere with action of L-dopa by promoting methylation. Concomitant administration of L-dopa and SAMe might potentially amplify, distort, or harmonize endogenous L-dopa and SAMe equilibrium. Research lacking to provide conclusive advice.	Concomitant use could aggravate symptoms or interfere with drug action. If clinically appropriate, may need to modify drug dosage. Monitor closely and titrate.
Oral contraceptives (OCs) ☼	By enhancing liver detoxification, glutathione production, and related metabolic processes, SAMe may protect against tendency of OCs to raise cholesterol saturation of bile by increasing biliary cholesterol secretion. Clinical trials warranted to follow and validate findings from supportive indirect research.	Coadministration may be beneficial in patients at risk of hepatobiliary dysfunction.
Ursodeoxycholic acid (UDCA) Chenodeoxycholic acid (CDCA) ⊕⊕	Both UDCA and SAMe can be efficacious in treatment of conditions related to hepatobiliary dysfunction and disease, including pruritus and intrahepatic cholestasis of pregnancy (ICP). UDCA was more effective than SAMe in controlling some symptoms, but research indicates that coadministration can increase efficacy and reduce potential fetal toxicity of UDCA.	Coadministration may be beneficial in patients at risk of hepatobiliary dysfunction, particularly ICP.
Venlafaxine Selective serotonin reuptake inhibitor and serotonin-norepinephrine reuptake inhibitor (SSRI and SNRI) Antidepressants ⊕⊕	Coadministration of SAMe with SSRIs, including venlafaxine, may augment therapeutic effect, particularly in individuals with partial or resistant responses to standard antidepressant pharmacotherapy. Mechanisms of action not fully elucidated, but preliminary evidence suggests minimal adverse effects.	Coadministration may be beneficial. May need to modify drug dosage. Monitor and titrate.

NAC, N-acetylcysteine; *CNS*, central nervous system.

NUTRIENT DESCRIPTION

Chemistry and Forms

Sulfuradenosylmethionine, S-adenosyl-L-methionine; S-adenosylmethionine butanedisulfonate, S-adenosylmethionine tosylate.

Physiology and Function

S-Adenosylmethionine (SAMe) is a naturally occurring compound functioning in a multitude of biochemical reactions and biosynthetic processes throughout the central nervous system (CNS), liver, connective tissue, and detoxification systems and within cellular metabolic activities. Dietary methionine is primarily metabolized in the liver, where it is combined with adenosine triphosphate (ATP) to form SAMe in a reaction catalyzed by methionine adenosyltransferase I/III (MAT I/III), the product of the MAT1A gene, which is exclusively expressed in the liver. SAMe serves as a precursor molecule to three main metabolic pathways within all cells: methylation, transulfuration, and aminopropylation.

S-Adenosylmethionine is the body's main biological methyl donor. After donating a methyl group in the synthesis of nucleic acids (DNA and RNA), choline, creatine, carnitine, proteins, phospholipids, catecholamines, epinephrine, and various neurotransmitters, SAMe is converted to S-adenosylhomocysteine (SAH). Subsequent *trans*-sulfuration reactions enable and regulate formation of sulfur-containing amino acids such as cysteine, glutathione, and taurine. After donating sulfur in this way, SAH gives up adenosine and is rapidly metabolized to homocysteine. Through the pathway known as ***aminopropylation***, SAMe is metabolized to decarboxylated SAMe and functions as a cofactor in the synthesis of polyamines, including spermidine, puescine, and spermine, which are essential for cellular growth and differentiation, gene expression, DNA repair, protein phosphorylation, and neuron myelination and regeneration. As a key facilitator of phosphatidylcholine synthesis, SAMe plays a role in promoting flexible and responsive cellular membranes and supports healthy bile production and flow. SAMe influences levels of 5-hydroxyindoleacetic acid (5-HIAA), a serotonin metabolite, and homovanillic acid, a dopamine metabolite, in the cerebrospinal fluid (CSF) and appears to cross the blood-brain barrier via carrier-mediated transport.

NUTRIENT IN CLINICAL PRACTICE

Known or Potential Therapeutic Uses

Human clinical trials investigating SAMe have reported positive outcomes in the treatment of a range of conditions, reflecting the broad and diverse functions of this substance in

human physiology. In particular, researchers have focused on depression, osteoarthritis, and liver disorders. Although a number of studies have shown clinical benefit, most have been limited by small numbers, brief duration, and preliminary or flawed design. Further, the research findings from human trials cannot be extrapolated readily to self-prescribed use or typical clinical practice, since oral dosages in European clinical trials have usually been significantly higher than those typically used by many individuals, and many studies have used intravenous (IV) or intramuscular (IM) modes of administration.

Historical/Ethnomedicine Precedent

S-Adenosylmethionine has not been used historically as an isolated nutrient.

Possible Uses

Alzheimer's disease, attention deficit–hyperactivity disorder (ADHD), cardiovascular disease, cirrhosis, dementia, depression, fibromyalgia, Gilbert's syndrome, infertility (male), insomnia, intrahepatic cholestasis of pregnancy, migraine, osteoarthritis, rheumatoid arthritis, Sjögren's syndrome, vacuolar myelopathy.

Dietary Sources

Methionine, from which SAMe is formed, can be obtained from a variety of dietary sources, but SAMe itself is not available through foods in any significant amounts. Dietary deficiencies in methionine, folate, or vitamin B_{12} can reduce SAMe levels.

Nutrient Preparations Available

S-Adenosylmethionine butanedisulfonate, *S*-adenosylmethionine tosylate.

In Europe, pharmaceutical preparations of SAMe are available mainly as IV, IM, and oral forms. In the United States, SAMe is primarily available in an over-the-counter (OTC) nutraceutical oral form as a capsule or tablet. SAMe is extremely hygroscopic and highly unstable; enteric-coated tablets packaged in foil or foil blister packs are considered the most stable form to avoid degradation.

Dosage Forms Available

Enteric-coated tablets. Parenteral preparations are available in Europe.

Source Materials for Nutrient Preparations

Biofermentation or synthesis from adenosine and methionine, generally complexed with a stabilizing salt, such as tosylate, disulfate tosylate, disulfate ditosylate, or 1,4-butanedisulfonate.

Dosage Range

Adult

Dietary: Not applicable.
Estimated safe and adequate daily dietary intake: Not applicable.
Average U.S. daily intake: Not applicable.
Recommended dietary allowance (RDA): None established.
Supplemental/Maintenance: Not applicable.
Pharmacological/Therapeutic: 400 mg three or four times daily, based on clinical trials.
Oral: 200 to 1600 mg daily.

Adequate dose-escalation studies using the oral formulation of SAMe have yet to be performed to demonstrate the most effective oral dose of SAMe.

The most common dosage is 400 mg daily, even though this level is significantly below the efficacy threshold indicated by research and clinical experience. Its relatively high cost has often been considered a limiting factor in the effective use of SAMe as a nutraceutical, especially when self-prescribed.
Toxic: No dietary reference intake (DRI) has been set for *S*-adenosylmethionine.

Pediatric (< 18 Years)

No guidelines have been established for therapeutic or toxic dosage levels of SAMe for infants or children. Use within such populations is not usually recommended as appropriate.

Laboratory Values

Plasma levels of SAMe. Levels of L-methionine *S*-adenosyltransferase activity in erythrocytes, SAMe concentrations in CSF, and concentrations of SAMe and *S*-adenosylhomocysteine (SAH) in whole blood have also been used in clinical trials.

SAFETY PROFILE

Overview

In clinical trials and reported clinical use, SAMe has generally been well tolerated and considered safe.

Nutrient Adverse Effects

No toxic effects have been reported in research or clinical experience involving SAMe. Dry mouth, nausea, restlessness, and skin rashes are among the several minor adverse effects occasionally associated with SAMe intake and generally reported at higher doses. One case report of "serotonin syndrome" involving concomitant use of IM SAMe (100 mg/day) and clomipramine (75 mg/day) represents the most severe adverse event known.[1-4]

Adults

Mutagenicity: Research thus far indicates that SAMe is nonmutagenic in vitro and in vivo, even using high doses.

Adverse Effects Among Specific Populations

S-Adenosylmethionine use may trigger a manic episode in individuals with bipolar disorder.[5-7]

Pregnancy and Nursing

The safety of SAMe use in pregnant or breast-feeding women has not been established. However, several studies investigating SAMe in the treatment of intrahepatic cholestasis of pregnancy (ICP) have reported the agent as apparently safe during pregnancy.

Infants and Children

The safety of SAMe administration in infants and children has not been established.

Contraindications

Bipolar disorder, migraines, Parkinson's disease; individuals with active bleeding.

Precautions and Warnings

Given that SAMe is a precursor to homocysteine and that methionine may elevate homocysteine, it would be prudent to assess homocysteine levels before treating with SAMe in individuals with a significant family history of coronary heart disease.

INTERACTIONS REVIEW

Strategic Considerations

S-Adenosylmethionine's central role in several critical metabolic pathways indicates that both excessive intake and drug-induced depletion are likely to produce significant consequences. Well-designed studies will be required to clarify and articulate the particulars of these patterns in a systematic manner. Likewise, further research is needed to determine therapeutic approaches to synergistic use of SAMe as part of integrative therapeutics employing the nutraceutical in conjunction with various conventional therapies for treatment of the conditions for which SAMe shows promise.

The issue of SAMe use by individuals diagnosed with bipolar disorder continues to be controversial; well-designed research is needed to assess its efficacy as a therapeutic agent, alone or in conjunction with conventional pharmacological treatments.

The scientific understanding of the physiology and pharmacology of SAMe is generally in a preliminary state, particularly with regard to genetic variability and its pharmacogenomic implications. In particular, the critical roles of SAMe in the areas of DNA methylation, neurotransmitter self-regulatory processes, and hepatic conjugation of pharmaceutical agents all deserve continued research and will undoubtedly reveal significant implications for SAMe's therapeutic application and interactions with other medications. Recent clinical trial data suggest that SAMe appears to augment the antidepressant effect of SSRI and SSRI/SNRI agents. Large, randomized, placebo-controlled trials addressing the difficult clinical problem of antidepressant-refractory depression are warranted.

NUTRIENT-DRUG INTERACTIONS

Acetaminophen

Acetaminophen (APAP, paracetamol; Tylenol); combination drugs: acetaminophen and codeine (Capital and Codeine; Phenaphen with Codeine; Tylenol with Codeine); acetaminophen and hydrocodone (Anexsia, Anodynos-DHC, Co-Gesic, Dolacet, DuoCet, Hydrocet, Hydrogesic, Hy-Phen, Lorcet 10/650, Lorcet-HD, Lorcet Plus, Lortab, Margesic H, Medipain 5, Norco, Stagesic, T-Gesic, Vicodin, Vicodin ES, Vicodin HP, Zydone); acetaminophen and oxycodone (Endocet, Percocet 2.5/325, Percocet 5/325, Percocet 7.5/500, Percocet 10/650, Roxicet 5/500, Roxilox, Tylox); acetaminophen and pentazocine (Talacen); acetaminophen and propoxyphene (Darvocet-N, Darvocet-N 100, Pronap-100, Propacet 100, Propoxacet-N, Wygesic), acetaminophen, butalbital, and caffeine (Fioricet).

Interaction Type and Significance

○ **Prevention or Reduction of Drug Adverse Effect**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

S-Adenosylmethionine reduces acetaminophen hepatotoxicity and lethality by metabolism of the active moiety to glutathione.

Research

In mouse models, SAMe (intraperitoneal administration, 1 g/kg or 2.5 mmol/kg) within 1 to 5 hours reduced depletion of plasma and liver glutathione, liver damage, and release of aspartate transaminase (AST) after acetaminophen administration.[8,9] Other researchers concluded that SAMe presented a therapeutic alternative to *N*-acetylcysteine (NAC) as an antidote for poisoning with acetaminophen.[10]

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Further research is indicated to confirm the efficacy and determine most effective dosage levels for use of SAMe, in place of or in conjunction with NAC, as an antidote in the treatment of acetaminophen poisoning.

Imipramine and Other Tricyclic Antidepressants

Evidence: Imipramine (Janimine, Tofranil).
Extrapolated, based on similar properties: Clomipramine (Anafranil)
Similar properties but evidence lacking for extrapolation: Amitriptyline (Elavil); combination drug: amitriptyline and perphenazine (Etrafon, Triavil, Triptazine); amoxapine (Asendin), desipramine (Norpramin, Pertofrane), doxepin (Adapin, Sinequan), nortriptyline (Aventyl, Pamelor), protriptyline (Vivactil), trimipramine (Surmontil).

Interaction Type and Significance

Effect and Mechanism of Action

S-Adenosylmethionine accelerates the onset of action of imipramine. Experiments using rats demonstrated that SAMe prevents the 5-HT(1A) receptor upregulation induced by acute imipramine in the frontal cortex.[11] SAMe and tricyclic antidepressants (TCAs) exert potentially similar influences on the CNS and together can generate an additive or synergistic effect.

Research

Numerous clinical trials have investigated the efficacy of SAMe in the treatment of various degrees of depression, often in comparison to TCAs, particularly imipramine. TCAs and SAMe have both been used successfully in treatment of depression; double-blind clinical studies show approximately equivalent efficacy, both superior to placebo, with TCAs associated

with more frequent adverse events and SAMe being better tolerated. Pancheri et al.[12] estimated IM 400 mg/day SAMe to be comparable to oral 150 mg/day imipramine in terms of antidepressive efficacy. Although many clinical trials of SAMe have involved IM, parenteral, or other modes of administering SAMe, oral administration of SAMe has demonstrated antidepressant activity, independent of its combination with imipramine or other antidepressants.[13]

Preliminary research has focused on the concomitant administration of these two agents with promising implications. In a double-blind clinical trial with 40 subjects receiving oral imipramine (150 mg/day initially and then according to symptoms), half also received IM 200 mg/day SAMe, and the other half also received placebo. The patients receiving the SAMe-imipramine combination reported a more rapid decrease in depressive symptoms than did those in the placebo-imipramine group.[14]

Report

In 1993, Iruela et al.[15] published a case report describing an episode of "serotonin syndrome" in a woman after combining IM 100 mg SAMe daily, with 75 mg/day clomipramine.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Physicians prescribing imipramine or other TCAs may consider use of SAMe within an integrative strategy combining the two agents and using SAMe as a support during weaning from TCA therapy. However, the potential for therapeutic synergy also invokes the risk of excessive pharmacological response. A clear need exists for well-designed clinical studies with larger numbers of subjects and a variety of combination therapies to determine conclusively which patients will benefit from conventional antidepressants, SAMe, or some combination and to establish appropriate dosage levels and therapeutic protocols. Pending such evidence, individuals should be dissuaded from unsupervised concomitant use of SAMe and TCAs or other antidepressant medications.

Significant potential exists for safe and effective therapy using coadministration within the context of integrative care, providing close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics. Clinical trials investigating the use of SAMe for treatment of depression suggests that an effective dose could be anywhere in the range of 800 to 1600 mg daily. Any concomitant use of SAMe and a TCA such as imipramine would need to be determined on the basis of the relative dose of the antidepressant and the particular needs of the individual being treated.

Levodopa and Related Antiparkinsonian Medications

Levodopa (L-dopa; Dopar, Larodopa); combination drugs: levodopa and benserazide (co-beneldopa; Madopar); levodopa and carbidopa (Atamet, Parcopa, Sinemet, Sinemet CR); levodopa, carbidopa and entacapone (Stalevo).

Related antiparkinsonian medications: Carbidopa (Lodosyn), selegiline (deprenyl, L-deprenil, L-deprenyl; Atapryl, Carbex, Eldepryl, Jumex, Movergan, Selpak).

Effect and Mechanism of Action

S-Adenosylmethionine levels tend to be low in individuals with Parkinson's disease, and levodopa therapy depletes the body of SAMe. However, SAMe may contribute to Parkinson-like motor impairments and interfere with the action of L-dopa. Thus, the dynamic equilibrium between endogenous L-dopa and SAMe can potentially be amplified, distorted, or harmonized by the introduction of exogenous L-dopa and SAMe.

SAMe promotes methylation and, as suggested by both rodent and human studies, excessive methylation can cause depletion of dopamine, is associated with Parkinson's disease, and can interfere with the effects of L-dopa. SAMe is the rate-limiting endogenous methyl donor, and its biochemical roles include the metabolism of dopamine and the synthesis of acetylcholine. Thus, SAMe may produce effects that resemble the changes that occur in Parkinson's disease, such as hypokinesia, tremor, rigidity, and abnormal posture. Therefore, SAMe may play a role in Parkinson-like motor impairments, particularly under conditions of excessive SAMe-dependent methylation.[16-18]

Levodopa is administered with dopa decarboxylase inhibitors (DDIs) to prevent its peripheral degradation. This increases conversion of levodopa to 3-*O*-methyldopa (3-OMD) by catechol-*O*-methyltransferase (COMT). SAMe serves as methyl donor for this *O*-metabolization of levodopa, with resulting conversion of SAMe to total homocysteine (tHcy) via *S*-adenosylhomocysteine (SAH).[19]

Research

Studies of the interaction between L-dopa and SAMe, both endogenous and exogenous, reveal several significant trends, but no conclusive patterns of substantive evidence have confirmed a safe and effective approach to clinical management. Whereas some evidence suggests that individuals with Parkinson's disease may benefit from SAMe therapy, other research indicates that SAMe may deplete dopamine, aggravate motor symptoms, and possibly block the intended therapeutic action of L-dopa.

In two early studies, Charlton et al.[16] and Crowell et al.[20] found that exogenous SAMe intake was associated with Parkinson-like symptoms in rats, specifically decreases in motor activity. Subsequent research with human subjects undergoing treatment of Parkinson's disease with L-dopa showed that L-dopa reacts avidly with SAMe to produce 3-OMD.[21]

Levodopa has been shown to deplete the concentration of SAMe in the brain and increase tHcy levels.[19,22] This depletion pattern may contribute to the depression often experienced by individuals with Parkinson's disease and may constitute a significant factor in the adverse effects associated with levodopa therapy.[22-23] General evidence regarding the function of SAMe and preliminary research both suggest that SAMe administration could benefit individuals with Parkinson's disease through positive effects on the depression and impaired cognitive function typically associated with the condition.[23] A double-blind, crossover study published by Carrieri et al.[24] in 1990 demonstrated beneficial effects of SAMe (400 mg orally, twice daily, plus 200 mg daily intramuscularly), versus placebo, against depression in 21 patients with Parkinson's disease. Parkinsonian symptoms appeared to be unchanged, adverse

effects were moderate and of brief duration, and there was no indication that the effectiveness of levodopa had been reduced. Likewise, in a more recent (2000) open-label pilot study involving 13 subjects with Parkinson's disease and comorbid depression, Di Rocco et al.[24a] found that 10 of the 11 patients who completed the clinical trial demonstrated at least a 50% improvement on the 17-point Hamilton Depression Scale (HDS) after 800 to 3600 mg SAMe daily for 10 weeks.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

The emerging pattern of evidence reflects the delicate interplay and dynamic equilibrium between L-dopa and SAMe. On the one hand, individuals with Parkinson's disease tend to be deficient in SAMe, inclined to depression, and subject to the depleting effects of levodopa therapy. On the other hand, SAMe could in theory contribute to excessive methylation, which appears to exacerbate motor impairments similar to parkinsonism, and concomitant SAMe may interfere with the therapeutic action of levodopa. Furthermore, the significant adverse effects associated with L-dopa (or carbidopa/levodopa) therapy cannot be easily overlooked, whereas SAMe is generally considered to produce minor adverse effects. Well-designed clinical trials with substantial numbers of human subjects will be required to clarify the diverse and paradoxical findings of the available preliminary research.

The possibility of enhanced synergistic benefits from combined therapy needs to be considered in light of the reasonable risk of serious exacerbation of symptoms. Given the weight of the evidence and the significant risk probability, it would be prudent to consider unsupervised and unmonitored use of SAMe during levodopa therapy as contraindicated. SAMe may benefit the person with Parkinson's disease as a whole while aggravating the pathophysiology.

The question of SAMe administration, particularly in conjunction with levodopa therapy, may be a matter of determining the individual (and dynamic) balance of SAMe depletion and excessive methylation effects or attendant risk. At this time, the balance of the evidence available warrants a cautionary avoidance of SAMe intake by individuals with Parkinson's disease, pending more conclusive research confirming safety and efficacy. In cases where SAMe administration is indicated by determination of a deficiency or depletion pattern and the broader clinical picture, any such use should only be undertaken within the context of close supervision and regular monitoring by health care professionals trained and experienced in both conventional pharmacology and nutritional therapeutics. In some of these individuals, levodopa dosage might need to be increased to compensate for any potential interference caused by SAMe coadministration. Given the lack of a comprehensive understanding of the pathophysiological processes involved and the complete implications of either of the therapeutic interventions, no dosage ranges for SAMe (or concomitant levodopa) can reasonably be suggested without reference to the particular individual being treated, his or her peculiar characteristics and needs, and clinical response. An integrative approach to personalized care will generally emphasize respecting and enabling, rather than imposing on or obstructing, the normal feedback cycles and self-regulatory processes involved in these neurotransmitters, their complex interrelationships, and pervasive influences.

Oral Contraceptives: Monophasic, Biphasic, and Triphasic Estrogen Preparations (Synthetic Estrogen and Progesterone Analogs)

Ethinyl estradiol and desogestrel (Desogen, Ortho-TriCyclen).
Ethinyl estradiol and ethynodiol (Demulen 1/35, Demulen 1/50, Nelulen 1/25, Nelulen 1/50, Zovia).
Ethinyl estradiol and levonorgestrel (Alesse, Levlen, Levlite, Levora 0.15/30, Nordette, Tri-Levlen, Triphasil, Trivora).
Ethinyl estradiol and norethindrone/norethisterone (Brevicon, Estrostep, Genora 1/35, GenCep. 1/35, Jenest-28, Loestrin 1.5/30, Loestrin1/20, Modicon, Necon 1/25, Necon 10/11, Necon 0.5/30, Necon 1/50, Nelova 1/35, Nelova 10/11, Norinyl 1/35, Norlestin 1/50, Ortho Novum 1/35, Ortho Novum 10/11, Ortho Novum 7/7/7, Ovcon-35, Ovcon-50, Tri-Norinyl, Trinovum).
Ethinyl estradiol and norgestrel (Lo/Ovral, Ovral).
Mestranol and norethindrone (Genora 1/50, Nelova 1/50, Norethin 1/50, Ortho-Novum 1/50).
Related, internal application: Etonogestrel/ethinyl estradiol vaginal ring (Nuvaring).

Effect and Mechanism of Action

Oral contraceptives (OCs) raise the cholesterol saturation of bile by increasing biliary cholesterol secretion.[25] SAMe enables liver detoxification and related metabolic processes, including glutathione production.

Research

Some women experience adverse reactions to the synthetic estrogens in OCs, including dysfunctional liver bile production, especially bile cholesterol supersaturation.[26] In particular, women with past histories of intrahepatic cholestasis of pregnancy (ICP), a relatively rare condition, exhibit an exaggerated genetic sensitivity to estrogens, which may express as abnormal hepatic reactivity to OC intake and increased risk of developing gallbladder disease. Studies have provided findings supporting the efficacy of SAMe in the treatment of ICP.[27,28] In a 1984 preliminary report of a controlled randomized trial, Di Padova[29] and a group of Italian researchers found that SAMe antagonizes OC-induced bile cholesterol supersaturation in healthy women. In a related small study published in 1988, Frezza et al.[30] found that oral SAMe (800 mg daily for 2 weeks) protects women with previous ICP from ethinyl estradiol–induced liver toxicity and normalizes bile cholesterol saturation index (CSI) in women who secrete lithogenic bile. These researchers concluded that SAMe acts as a physiological antidote against estrogen hepatobiliary toxicity caused by OCs in susceptible women.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

Weight gain in women using OCs has been debated for decades, and concern remains over estrogen's role in contributing to liver dysfunction and increased susceptibility to weight gain and gallbladder disease among women entering their fourth decade. Although ICP is a relatively uncommon condition, the research into its pathophysiology suggests that SAMe administration might counter the adverse effects on hepatobiliary function and fat metabolism experienced by some women in relation to estrogen metabolism, particularly under the potential stress of OCs. In this situation the emerging tools of pharmacogenomics may provide effective means for assessing relative risk among women in relation to estrogen stress and exogenous hormones in particular. Further, the trend toward decreasing the estrogen dosage in OCs has undoubtedly reduced the frequency and degree of bile cholesterol

supersaturation and other, more subtle manifestations of hepatobiliary dysfunction among susceptible women.

Clinicians might consider concomitant SAMe as a supportive adjunctive therapy, with minimal attendant risk, for female patients prescribed OCs (or in other cases involving potential liver and/or gallbladder reactivity to estrogen, including hormone replacement therapy) who have a history of or now exhibit changes in bile function, fat metabolism, or other indication of estrogenic distress. A dosage in the range of 200 to 400 mg per day, in divided doses, would be a reasonable starting point, subject to individual patient characteristics and needs and tailored to clinical response.

Ursodeoxycholic Acid and Chenodeoxycholic Acid

Evidence: Ursodeoxycholic acid (UDCA; ursodiol; Actigall, Destolit, Urdox, Urso, Ursofalk, Ursogal).
Extrapolated, based on similar properties: Chenodeoxycholic acid (CDCA, chenodiol; Chenix).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ◉ **Emerging**

Effect and Mechanism of Action

Ursodeoxycholic acid (UDCA) is used in the treatment of several hepatobiliary conditions to reduce pruritus, treat cholelithiasis, and improve biochemical parameters, particularly bile constituents. The medical use of bear gallbladder *(Xiongdan)* in Chinese medicine was first recorded in the *Yao Xing Lun* ("Treatise on the Nature of Medicinal Herbs"), a now-lost text from the Song Dynasty that originated in the early Tang Dynasty (ca. 600 CE). Currently, the material is produced synthetically or extracted from byproducts of slaughterhouses. In many respects, UDCA inhabits the intermediary zone where traditional "herbal" medicine and pharmaceuticals overlap. Within conventional practice, UDCA is considered the only therapeutic modality whose effectiveness in the treatment of ICP is supported by evidence from controlled trials.[28,31] Similarly, UDCA is used for symptomatic relief of itching in the treatment of primary sclerosing cholangitis. UDCA is also used in the treatment of primary biliary cirrhosis to improve liver biochemistry, increase survival, and delay liver transplantation. Recent research on the use of UDCA in the treatment of Huntington's disease is considered promising.

S-Adenosylmethionine exerts numerous metabolic effects within the liver that can assist detoxification functions and alter bile formation in ways that may provide an additive effect with, or alternative to, UDCA as a therapeutic agent.

Research

In a randomized clinical trial published in 1996 involving 20 women with ICP in the last trimester of pregnancy, Floreani et al.[32] compared the effects of SAMe (1000 mg/day intramuscularly) and UDCA (450 mg/day). The treatment was continued until delivery, at least 15 days, in all women. They found that UDCA was more effective than SAMe in controlling pruritus and total bile acids. Subsequently Nicastri et al.[29] conducted a randomized placebo-controlled study involving 32 women exhibiting ICP who were divided into four groups. These researchers determined that, after treatment for 20 days, a "combination of ursodeoxycholic acid and *S*-adenosylmethionine is more effective than placebo and than either drug alone." Roncaglia et al.[33] conducted a randomized controlled trial of oral UDCA (300 mg twice daily) and oral *S*-adenosyl-L-methionine (500 mg twice daily) in the treatment of severe gestational cholestasis. They found that women receiving UDCA demonstrated a significantly greater improvement in tests of liver function (i.e., concentration of serum bile acids, aspartate transaminase [AST], alanine transaminase [ALT], and bilirubin) compared with those receiving SAMe. Duration of therapy was significantly greater in women receiving UDCA compared with SAMe.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

A relatively rare disorder, ICP appears to be related to an exaggerated genetic sensitivity to estrogens and manifests during pregnancy with pruritus and icterus as the chief complaints. Although ICP is generally considered as carrying minimal medical risk to the mother, it is regarded as presenting significant risk of perinatal mortality to the fetus, preterm delivery, fetal distress, and meconium staining. Elevated alkaline phosphatase and serum bilirubin levels are characteristic, as are other increased values of parameters indicating altered liver function and bile composition. The trend in clinical trials reveals a pattern of research focusing on the relative efficacy of UDCA and SAMe in the treatment of ICP. There is general agreement that UDCA represents a therapeutic agent supported by both clinical experience and research evidence. The available studies, although all small in size, suggest that a combination therapy provides synergistic, or at least additive, therapeutic efficacy. Given the consensus and evidence that both substances are safe during pregnancy, for both mother and fetus, such approaches deserve further research and empirical investigation. The utility of SAMe in the treatment of other conditions for which UDCA has shown efficacy has yet to be investigated in well-designed clinical trials of adequate size.

Venlafaxine and Related Selective Serotonin Reuptake Inhibitor and Serotonin-Norepinephrine Reuptake Inhibitor (SSRI and SNRI) Antidepressants

Evidence: Venlafaxine (Effexor).
Extrapolated, based on similar properties:
SSRI: Citalopram (Celexa), duloxetine (Cymbalta), escitalopram (S-citalopram; Lexapro), fluoxetine (Prozac, Sarafem), fluvoxamine (Faurin, Luvox), paroxetine (Aropax, Deroxat, Paxil, Seroxat), sertraline (Zoloft).
SSRI/SNRI: Duloxetine (Cymbalta).

Interaction Type and Significance

⊕⊕ **Beneficial or Supportive Interaction, with Professional Management**

Probability: **2. Probable**

Evidence Base: ○ **Preliminary**

Effect and Mechanism of Action

S-Adenosylmethionine and selective serotonin reuptake inhibitors (SSRIs) are both known to benefit individuals with depression. However, research data are as yet inadequate to elucidate fully the mechanisms of action involved and whether the effect is additive or synergistic.

Research

Alpert et al.[34] conducted an open clinical trial to evaluate the safety, tolerability, and efficacy of oral SAMe as an antidepressant adjunct among partial responders and nonresponders to

serotonin reuptake inhibitors or venlafaxine, a dual selective serotonin reuptake inhibitor and serotonin-norepinephrine reuptake inhibitor (SSRI/SNRI). They administered *S*-adenosyl-L-methionine tosylate (800-1600 mg) to 30 antidepressant-treated adult outpatients with persisting major depressive disorder. At the end of the 6-week treatment period, these researchers observed a response rate of 50% and a remission rate of 43% after augmentation of SSRI or venlafaxine with SAMe and reported minor gastrointestinal distress and headaches as the primary adverse effects.[34] These findings indicate that further research in the form of a well-designed, adequately powered placebo-controlled clinical trial is warranted to further determine the efficacy, assess safety parameters, and refine clinical management guidelines for the integrative treatment of depression using SAMe and venlafaxine or SSRI antidepressants.

Nutritional Therapeutics, Clinical Concerns, and Adaptations

A review of clinical practice and preliminary evidence suggests an emerging, but not yet coherent or articulate, proposition suggesting that SAMe, in graduated dosages in the range of 400 to 800 mg twice daily, can be used adjunctively with SSRI medications to enhance the clinical effectiveness of treatment for depression and other appropriate conditions. The variable mechanisms of action among different SSRIs, along with individual pharmacogenomic variability, life stage, and gender factors and other metabolic influences, may account for differing therapeutic responses and occurrences of adverse effects.

Such an integrative therapeutic strategy warrants close supervision and regular monitoring within the context of coordinated care by health care providers trained and experienced in both clinical nutrition and conventional pharmacology. The concomitant use of SAMe and SSRI medications and/or SSRI/SNRI agents such as venlafaxine should not be used outside of such context of active clinical management. Even though preliminary findings indicate a minimal level of adverse effects, unsupervised coadministration of SSRI drugs with SAMe must still be treated as a potential risk for higher incidence of serotonin-associated unintended effects and adverse events, pending more conclusive evidence. A rapid onset of symptoms indicating an adverse response, particularly CNS toxicity, is highly probable in the unlikely event that a serotonin syndrome or other adverse event does develop.

THEORETICAL, SPECULATIVE, AND PRELIMINARY INTERACTIONS RESEARCH, INCLUDING OVERSTATED INTERACTIONS CLAIMS

Anticoagulant and Antiplatelet Medications

Anticoagulant and Antiplatelet Medications

Limited in vitro studies of SAMe's effect on platelet activation, particularly platelet thromboxane and vascular prostacyclin, suggest that use by individuals with active bleeding disorders or undergoing anticoagulant therapy may be contraindicated, at a level of risk perhaps comparable to aspirin. The range of cautions and contraindications will be extensive in the event that such concerns are confirmed by high-quality clinical trials or a consistent pattern of well-documented case reports. Toward clarifying such potentially significant issues, physicians treating susceptible individuals or prescribing potentially interacting medications are advised to be cognizant of the plausibility of such concerns and document and report suspicious events in a thorough and systematic manner.[35,36]

Monoamine Oxidase (MAO) Inhibitors

MAO-A inhibitors: Isocarboxazid (Marplan), moclobemide (Aurorix, Manerix), phenelzine (Nardil), procarbazine (Matulane), tranylcypromine (Parnate).

MAO-B inhibitors: Selegiline (deprenyl, L-deprenil, L-deprenyl; Atapryl, Carbex, Eldepryl, Jumex, Movergan, Selpak); pargyline (Eutonyl); rasagiline (Azilect).

Concerns have been raised that unmanaged exogenous SAMe could produce an undesirable additive effect if taken in conjunction with MAO inhibitors or SSRI antidepressants. Although such interactions might be plausible, no readily available published evidence from animal studies or human trials supports the hypothesis that such an interaction actually occurs or describes its character and implications in human subjects. In the event that such a pattern of interaction should come to light, the example of TCAs suggests that synergistic coadministration might be efficacious within the context of integrative case management and personalized therapeutic adaptations. Although classic MAO inhibitors are no longer widely used, the potentially catastrophic nature of their interactions would dictate extreme caution in combining a neurotransmitter modulator such as SAMe with MAO inhibitors in the absence of any clinical trial or published anecdotal experience with the combination.

Vidarabine

Evidence: Vidarabine (Ara-A, arabinoside; Vira-A).
Potential: Ribaviran (Copegus, Rebetol, Ribasphere, Vilona, Virazole).

The most common use of vidarabine is as an ophthalmic preparation for the treatment of herpes simplex virus types 1 and 2 (HSV-1 and HSV-2) in acute keratoconjunctivitis and recurrent superficial keratitis. The therapeutic action of vidarabine is achieved by interfering with viral DNA synthesis, specifically inhibition of *S*-adenosylhomocysteine hydrolase (SAH), methionine synthesis, and SAMe-dependent DNA methylation. Vidarabine cannot be given orally because it is metabolized in the gut, so it is usually administered intravenously or topically.[37-39]

The action of vidarabine indicates a potential risk for interfering with methionine function in humans and potentially inducing a depletion of methionine with extended use. Any such depleting effect on methionine status is likely to be gradual and cumulative, but evidence from human trials is lacking. Concomitant administration of SAMe (or methionine) could theoretically interfere with the therapeutic activity of vidarabine or related antiviral medications.

Although the mechanism of interaction between vidarabine and SAMe is obvious and incontrovertible, the recognition of this interaction and its potential adverse effects has not been acknowledged or addressed in published scientific research. Human studies are lacking to determine whether vidarabine might induce clinically significant methionine depletion and whether methionine administration might interfere with the medication's antiviral activity. Further research is warranted.

Physicians prescribing vidarabine for an extended period may want to present a patient with options for countering the potential adverse effects of this drug. Some nutritionally oriented health care professionals have found value in monitoring serum methionine in their patients taking vidarabine. Coadministration of methionine could be used to counter this adverse effect of vidarabine. Concomitant use of SAMe has not been studied in this regard but may be appropriate. However, due consideration is appropriate, and future research

could help clarify whether any such SAMe intake might be contraindicated as interfering with the intended therapeutic action of the medication.

NUTRIENT-NUTRIENT INTERACTIONS

5-Hydroxytryptophan (5-HTP)

The concomitant administration of SAMe with 5-HTP or other supplements or herbs thought to exert an antidepressant effect should be approached with caution and subject to close supervision and regular monitoring. Such therapeutic synergies are common in clinical practice and have a presumed history of empirical efficacy. However, the safety and effectiveness of such prescribing practices have yet to be studied in any well-designed and systematic clinical trials and must always be considered within the context of an evolving and personalized therapeutic plan managed by health care professionals trained and experienced in both conventional pharmacology and the appropriate herbal or nutritional disciplines.

Selenium

The toxicity of selenium at high dosages, especially in its inorganic forms, is largely attributable to its depletion of SAMe reserves. SAMe is the body's principal methyl donor, and the metabolism of inorganic selenium requires both extra methyl donors and higher levels of antioxidants on its way to becoming methylselenol.

The 40 citations for this monograph, as well as additional reference literature, are located under *S*-Adenosylmethionine on the CD at the back of the book.

5-Alpha (5α)-Reductase Inhibitors: Black Cohosh, Saw Palmetto
5-Hydroxytryptamine Receptor Agonists (Triptans): 5-HTP, Feverfew
Alpha-1-Adrenoceptor Antagonists: Saw Palmetto, Vitamin B_3

Cardiac Glycosides: Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice

Cephalosporin Antibiotics: Ginseng, Green Tea, Iron, Licorice, Probiotic Intestinal Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Chemotherapy (Various Cytotoxic Agents): Aloe, Eleuthero, Ginseng, Licorice, Omega-3 Fatty Acids, Vitamin A, Vitamin C, Vitamin E

Chemotherapy and Radiotherapy (Generally): Aloe, Ginseng, Melatonin, PABA, Reishi, Vitamin C, Vitamin E

Chemotherapy, Alkylating Agents: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Chemotherapy, Anthracyclines: Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, Turmeric (Curcumin), Vitamin B_2, Vitamin E

Chemotherapy, Antimetabolites: Echinacea, Eleuthero, Folic Acid, Vitamin B_3

Chemotherapy, Aromatase Inhibitor Hormonal Anticancer Therapies: Green Tea

Chemotherapy, Cytotoxic Antibiotics: Echinacea, Eleuthero, Ginseng, Licorice, Probiotic Intestinal Flora, Vitamin B_1, Vitamin K

Chemotherapy, Estrogens: Black Cohosh

Chemotherapy, GnRH Antagonists/LHRH Antagonists: Black Cohosh

Chemotherapy, LHRH Agonists: Black Cohosh, Vitamin D

Chemotherapy, Mitotic Inhibitors: Echinacea, Eleuthero, St. John's Wort

Chemotherapy, Topoisomerase II Inhibitors: St. John's Wort

Corticosteroids, Oral: Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Corticosteroids, Topical: Aloe, Green Tea, Licorice, Vitamin C

COX-1 Inhibitors (NSAIDs): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric (Curcumin), Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

COX-2 Inhibitors (NSAIDs): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric (Curcumin), Vitamin B_3, Vitamin C, Zinc

Cytochrome P450 1A2 Isoenzyme Substrates: Echinacea, Melatonin

Cytochrome P450 2C9 Isoenzyme Substrates: Melatonin

Cytochrome P450 3A4 Isoenzyme Substrates: Echinacea, Vitamin E

Diuretics, Combination Drugs: Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Erythropoiesis-Stimulating Agents: Dang Gui, Iron, Vitamin B_6, Vitamin C

Estrogen-Containing and Synthetic Estrogen Analog Medications: Arginine, Black Cohosh, Boron, Calcium, Copper, Dang Gui, DHEA, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Fibrates: Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Fluoroquinolone (4-Quinolone) Antibiotics: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Intestinal Flora, Vitamin B_1, Vitamin K, Zinc

GABA Analogs: Vitamin B_3

Ganglionic Blocking Agents: Vitamin B_3

Glucocorticoids, Systemic: See *Corticosteroids, Oral.*

Halogenated Inhalational Anesthetic Agents: Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Histamine (H_2) Receptor Antagonists: Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc

HMG-CoA Reductase Inhibitors (Statins): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Hormone Replacement Therapy, Estrogen/Progestin Combinations: Arginine, Black Cohosh, Boron, Calcium, Copper, Dang Gui, DHEA, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Hormone Replacement Therapy, Estrogen/Testosterone Combinations: Black Cohosh, Boron, Calcium, Copper, Dang Gui, DHEA, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Hormone Replacement Therapy, Estrogens: Arginine, Black Cohosh, Boron, Calcium, Copper, Dang Gui, DHEA, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Hormone Replacement Therapy, Progesterone: Vitamin D

Hormone Replacement Therapy, Progestins: Vitamin D

Imidazole Antibiotics: Probiotic Intestinal Flora, Vitamin B_2

Immunosuppressants (Generally): Echinacea

Laxatives (Generally): Licorice

Laxatives, Bulk-Forming Laxative Agents: Potassium, Vitamin B_2

Laxatives, Fast-Acting Laxative Agents: Potassium

Laxatives, Prescription Laxative Agents: Potassium

Laxatives, Stimulant: Calcium

Loop Diuretics: Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc

Macrolide Antibiotics: Calcium, Green Tea, Magnesium, Probiotic Intestinal Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Meglitinide Analog Oral Hypoglycemics: Chromium, Vitamin B_3

Mixed Alpha-1/Beta- Adrenoceptor Antagonists: Potassium

Monoamine Oxidase A (MAO-A) Inhibitors: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Monoamine Oxidase B (MAO-B) Inhibitors: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine

Narcotic Analgesics (Opioids): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Neuromuscular Blocking Agents: Magnesium

Nitrates: Arginine, Carnitine, Folic Acid, Vitamin C

Nitrofuran Antibiotics: Licorice

Nitroimidazole Antiprotozoals: Milk Thistle

Nonsteroidal Anti-Inflammatory Drugs (NSAIDs): See *COX-1 Inhibitors (NSAIDs)* or *COX-2 Inhibitors (NSAIDs).*

Nucleic Acid Synthesis Inhibitors, Antiviral: *S*-Adenosylmethionine (SAMe)

Oral Contraceptives (Synthetic Estrogen and Progesterone Analogues): Arginine, Calcium, Copper, Dang Gui, DHEA, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Oral Hypoglycemic Agents, Combination Drugs: DHEA, Ginkgo, Glucosamine Sulfate, Omega-3 Fatty Acids

Oral Hypoglycemic Agents: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric (Curcumin), Vitamin B_3

Penicillin Antibiotics: Ginseng, Green Tea

Peripheral Adrenergic Blocking Agents: Ephedra

Phenothiazines: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Phosphodiesterase-5 Inhibitors: Arginine

Photosensitizing Agents: St. John's Wort

Pivalate Prodrugs: Carnitine

Potassium-Sparing Diuretics: Arginine, Calcium, Folic Acid, Glucosamine Sulfate, Magnesium, Zinc

Progestin Oral Contraceptives, Implants, and Postcoital Contraceptives: Magnesium, St. John's Wort

Progestin-Estrogen Injectable Contraceptives: Magnesium

Progestins/Progesterone Analogs: Vitex; see Hormone Replacement Therapy, Estrogen/Progestin Combinations

Protease Inhibitors: Copper, Garlic, St. John's Wort, Vitamin C

Proton Pump Inhibitors: Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc

Purine Nucleoside Analog Antivirals: Astragalus

Quinolone Antibiotics: See *Fluoroquinolone (4-Quinolone) Antibiotics.*

Retinoids: Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Salicylates: Calcium, Omega-3 Fatty Acids, Policosanol, Vitamin K

Secale Alkaloids: Ephedra

Sedative-Hypnotics: Gotu Kola, Melatonin, Valerian

Selective Estrogen Receptor Modulators (SERMs): Black Cohosh, Dang Gui, Green Tea

Selective Serotonin Reuptake Inhibitor (SSRI) Antidepressants: Chromium, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Selective Serotonin Reuptake Inhibitor/Serotonin-Norepinephrine Reuptake Inhibitor (SSRI/SNRI) Antidepressants: 5-HTP, Ginkgo, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}

Serotonin Agonists: 5-HTP, Tryptophan

Stimulant Medications: 5-HTP; Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B_6, Vitamin C, Zinc

Stool Softeners: Potassium

Sulfonamide Antibiotics: Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Intestinal Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Sulfonylurea Oral Hypoglycemics: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric (Curcumin), Vitamin B_3

Surgery (Generally): Garlic, Ginkgo, St. John's Wort

Tetracycline Antibiotics: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Thiazide Diuretics: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Thiazide-like Diuretics: Glucosamine Sulfate, Potassium

Thiazolidinediones (Glitazones): Chromium, Vitamin B_3

Thrombolytic Agents: Astragalus

Thyroid Hormones: Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Triazolobenzodiazepines: Kava, St. John's Wort

Tricyclic Antidepressants: 5-HTP, Coenzyme Q10, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Urinary pH Modifiers: Ephedra

Vaccine Immunotherapies: Ginseng

Vitamin B_6–Depleting Drugs: Melatonin

13-*cis* Retinoic Acid (Isotretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

4-Aminosalicylic Acid (4-ASA) (Para-Aminosalicylic Acid): Vitamin B_{12}

5-Aminosalicylic Acid (5-ASA) (Mesalazine): Vitamin B_{12}

5-FU (Fluorouracil): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginkgo, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

6-Mercaptopurine (6-MP): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_3

6-Thioguanine (6-TG) (Thioguanine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_3

Abacavir: Aloe, Carnitine, Coenzyme Q10, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Abciximab: Cayenne, Ginger, Policosanol, *S*-Adenosylmethionine (SAMe)

Aberelix: Black Cohosh

Acarbose: Chromium, Vitamin B_3

Acebutolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Acenocoumarol (Nicoumalone): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acetaminophen: Dang Gui, Devil's Claw, Garlic, Gotu Kola, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C

Acetaminophen + Butalbital + Caffeine: Calcium, DHEA, Ephedra, Garlic, Gotu Kola, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Valerian, Vitamin B_2, Vitamin C

Acetaminophen + Chlorpheniramine + Dextromethorphan + Pseudoephedrine: Garlic, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C

Acetaminophen + Codeine: Garlic, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C

Acetaminophen + Dextropropoxyphene: Garlic, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C

Acetaminophen + Oxycodone: Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Acetaminophen + Pentazocine: Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Methionine, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Acetaminophen + Propoxyphene: Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Acetazolamide: Coenzyme Q10, Ephedra, Potassium

Acetohexamide: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Acetophenazine + Hydrocodone: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Acetylsalicylic Acid: Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acetylsalicylic Acid + Caffeine: Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Policosanol, Potassium, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acetylsalicylic Acid + Caffeine + Propoxyphene: Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acetylsalicylic Acid + Codeine: Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K

Acetylsalicylic Acid + Codeine + Butalbital + Caffeine: Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acetylsalicylic Acid + Dipyridamole (Extended-Release): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acetylsalicylic Acid + Oxycodone: Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acetylsalicylic Acid + Pentazocine: Calcium, Ephedra, Folic Acid, Ginseng, Gotu Kola, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, Phenylalanine, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin E

Acetylsalicylic Acid + Propoxyphene: Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Acitretin: Beta-Carotene, Calcium, Carnitine, Omega-3 Fatty Acids, Vitamin A, Vitamin E

Actidone (Cycloheximide): Dang Gui, Echinacea

Actinomycin D (Dactinomycin): Echinacea, Eleuthero, Ginseng, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K

Acyclovir: Aloe, Astragalus, Folic Acid, Reishi

Adalimumab: Echinacea
Adefovir Dipivoxil: Carnitine
Adinazolam: Kava, St. John's Wort
Agalsidase Beta: Echinacea, Eleuthero, Folic Acid, Vitamin B_1
Albendazole: Beta-Carotene, Vitamin A
Albuterol: Calcium, Magnesium, Potassium
Albuterol + Ipratropium Bromide: Calcium, Magnesium, Potassium
Alclometasone: Aloe, Green Tea, Licorice, Vitamin C
Aldesleukin: Astragalus, Echinacea, Melatonin
Alendronate: Calcium, Iron, Magnesium, Vitamin D, Zinc
Alfacalcidol: Vitamin D
All-*trans* Retinoic Acid (Tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E
Allopurinol: Carnitine, Copper, Iron, Tryptophan, Vitamin D
Almotriptan: 5-HTP, Feverfew, Tryptophan
Alprazolam: DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3
Alteplase, Recombinant, Parenteral: Astragalus
Altretamine: Vitamin B_6
Aluminum Carbonate Gel: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Zinc
Aluminum Hydroxide: Calcium, Cayenne, Chromium, Copper, Ephedra, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Zinc
Aluminum Hydroxide + Magnesium Hydroxide: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc
Aluminum Hydroxide + Magnesium Hydroxide + Calcium Carbonate + Simethicone: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc
Aluminum Hydroxide + Magnesium Hydroxide + Simethicone: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc
Aluminum Hydroxide + Magnesium Trisilicate: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc
Amcinonide: Aloe, Green Tea, Licorice, Vitamin C
Amikacin: Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Amiloride: Arginine, Calcium, Folic Acid, Glucosamine Sulfate, Magnesium, Potassium, Zinc
Amiloride + Hydrochlorothiazide: Arginine, Calcium, Coenzyme Q10, Folic Acid, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Aminosalicylic Acid (Para-Aminosalicylic Acid): Vitamin B_{12}
Amiodarone: Cascara, Echinacea, Magnesium, Potassium, Vitamin B_6, Vitamin E
Amitriptyline: 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Amitriptyline + Perphenazine: Coenzyme Q10, Echinacea, Milk Thistle, St. John's Wort, Vitamin B_{12}
Amlodipine: Calcium, Carnitine, DHEA, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Amlodipine + Benazepril: Arginine, Calcium, Cayenne, Coenzyme Q10, DHEA, Potassium, St. John's Wort
Ammonium Chloride: Ephedra
Amobarbital: DHEA, Gotu Kola, Valerian, Vitamin B_2
Amoxapine: 5-HTP, Coenzyme Q10, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Amoxicillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Amoxicillin + Clavulanic Acid: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Amphetamine: 5-HTP, Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B_6, Vitamin C, Zinc
Amphetamine + Dextroamphetamine: 5-HTP, Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B_6, Vitamin C, Zinc
Amphotericin B (AMB): Calcium, Echinacea, Magnesium, Potassium
Amphotericin, Liposomal: Echinacea
Ampicillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin C, Vitamin K, Zinc
Ampicillin + Sulbactam: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Amprenavir: Copper, Garlic, St. John's Wort, Vitamin C
Amyl Nitrate: Arginine, Carnitine, Folic Acid, Vitamin C
Anastrozole: Green Tea
Anesthesia, General: Alpha-Lipoic Acid, Ginger, Ginkgo, St. John's Wort
Anisindione: Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Anistreplase: Astragalus
Anthralin: Vitamin E
Aprobarbital: DHEA, Gotu Kola, Valerian, Vitamin B_2
Ara-A (Vidarabine): Methionine, Reishi, *S*-Adenosylmethionine (SAMe)
Ara-C (Cytarabine): Echinacea, Eleuthero, Folic Acid, Ginseng, Vitamin B_1
Arabinoside (Vidarabine): Methionine, Reishi, *S*-Adenosylmethionine (SAMe)
Ardeparin: Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C
Argatroban: Cayenne, DHEA, Policosanol
Aripiprazole: 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C
ASA: See *Acetylsalicylic Acid*.
Asathioprine (Azathioprine): Echinacea, Folic Acid, Vitamin B_3
Aspirin and Related Compounds: See *Acetylsalicylic Acid*.
Atazanavir: Copper, Garlic, St. John's Wort, Vitamin C
Atenolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Atenolol + Chlorthalidone: Arginine, Calcium, Coenzyme Q10, Policosanol, Potassium, Vitamin C
Atenolol + Nifedipine: Arginine, Calcium, Coenzyme Q10, Dang Gui, Magnesium, Policosanol, Potassium, St. John's Wort, Vitamin C
Atorvastatin: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol,

Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Atovaquone + Proguanil: Vitamin B_2

ATRA (Tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Atracurium: Ginger, Magnesium

Azathioprine: Echinacea, Folic Acid, Vitamin B_3

Azidothymidine (AZT; Zidovudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc

Azithromycin: Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

AZT (Zidovudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc

AZT + 3TC (Zidovudine + Lamivudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc

Aztreonam: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin C, Vitamin K, Zinc

Bacampicillin: Ginseng, Green Tea

Bacitracin: Licorice, Probiotic Flora, Vitamin K, Zinc

Baclofen: Phenylalanine

Beclomethasone Inhalant: Calcium

Beclomethasone Topical: Aloe, Green Tea, Licorice, Vitamin C

Benazepril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Bendrofluazide (Bendroflumethiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Bendrofluazide + Propranolol: Arginine, Coenzyme Q10, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Policosanol, Potassium, Vitamin D, Zinc

Benperidol: Milk Thistle, Phenylalanine

Benserazide: Folic Acid, Iron, *S*-Adenosylmethionine (SAMe), Vitamin B_6, Vitex

Benzthiazide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Benztropine: Vitamin B_3

Benzyl + Procaine Penicillin: Vitamin C

Bepridil: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Betamethasone: Aloe, Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Green Tea, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Betamethasone Topical: Aloe, Green Tea, Licorice, Vitamin C

Betanidine: Ephedra

Betaxolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Bexarotene: Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Bezafibrate: Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Bicalutamide: Black Cohosh, Vitamin D

Bisacodyl Tablets: Potassium

Bismuth Subsalicylate + Metronidazole + Tetracycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Bisoprolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Bivalirudin: Cayenne, DHEA, Policosanol

Bleomycin: Aloe, Echinacea, Eleuthero, Garlic, Ginseng, Licorice, Omega-3 Fatty Acids, Probiotic Flora, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin B_1, Vitamin C, Vitamin E, Vitamin K

Boldenone: Echinacea

Borate: Vitamin B_2

Boric Acid: Vitamin B_2

Brecanavir (GW640385): Copper, Garlic, St. John's Wort, Vitamin C

Bretylium: Ephedra

Brinzolamide (Ophthalmic Suspension): Potassium

Bromazepam: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Brotizolam: Kava, St. John's Wort

Buformin: Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Bumetanide: Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc

Buprenorphine: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Buprenorphine + Naloxone: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Bupropion: Melatonin

Buspirone: 5-HTP, St. John's Wort, Tryptophan

Busulfan: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Butabarbital: DHEA, Gotu Kola, Valerian, Vitamin B_2

Butalbital: DHEA, Gotu Kola, Valerian, Vitamin B_2

Butorphanol: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Butoxamine: Potassium

Caffeine: Calcium, Ephedra, Kava, Melatonin

Calcitonin: Calcium, Vitamin D

Calcitriol: Vitamin D

Calcium Acetate: Calcium

Calcium Carbonate: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin D, Zinc

Calcium Carbonate + Magnesium Hydroxide + Simethicone: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc

Camptothecin-11 (Irinotecan): Aloe, Ginseng, Omega-3 Fatty Acids, Vitamin A, Vitamin C, Vitamin E

Candesartan: Alpha-Lipoic Acid, Potassium

Candesartan + Hydrochlorothiazide: Alpha-Lipoic Acid, Potassium

Capecitabine: Echinacea, Eleuthero, Folic Acid, Vitamin B_3

Captopril: Arginine, Cayenne, Iron, Magnesium, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Captopril + Hydrochlorothiazide: Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Carbamazepine: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Carbenicillin: Ginseng, Green Tea

Carbenoxolone: Potassium

Carbidopa: 5-HTP, Folic Acid, Iron, Kava, *S*-Adenosylmethionine (SAMe), Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Carboplatin: Alpha-Lipoic Acid, Astragalus, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Ginger, Ginkgo, Ginseng, Milk Thistle, Selenium, Turmeric/Curcumin

Carteolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Carvedilol: Potassium

CDDP (Cisplatin): Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Calcium, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Feverfew, Ginger, Ginkgo, Ginseng, Magnesium, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Potassium, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin B_6, Vitamin C, Vitamin E, Zinc

Cedilanin-D (deslanoside): Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort

Cefaclor: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefadroxil: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefamandole: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefazolin: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefcapene Pivoxil: Carnitine

Cefdinir: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefditoren Pivoxil: Carnitine

Cefepime: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefetamet Pivoxil: Carnitine

Cefixime: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefoperazone: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefotaxime: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin C, Vitamin K, Zinc

Cefotetan: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefoxitin: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefpodoxime: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefprozil: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Ceftazidime: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Ceftibuten: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Ceftizoxime: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Ceftriaxone: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefuroxime: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Celecoxib: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin C, Zinc

Celiprolol: Potassium

Cephalexin: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cephapirin: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cephradine: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cerivastatin: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Certoparin: Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Chenodeoxycholic Acid (CDCA): *S*-Adenosylmethionine (SAMe), Vitamin B_3

Chlorambucil: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Chloramphenicol: Folic Acid, Iron, Licorice, Probiotic Flora, Vitamin B_{12}, Vitamin K, Zinc

Chlordiazepoxide: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Chlorhexidine Mouthwash: Iron, Licorice, Probiotic Flora, Vitamin K, Zinc

Chlorhexidine + Nystatin + Hydrocortisone: Iron, Licorice, Probiotic Flora, Vitamin K

Chlorimipramine (Clomipramine): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Chloroquine: Calcium, Magnesium, Vitamin B_2, Vitamin E

Chlorothiazide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Chlorotrianisene: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Chlorpromazine: Chromium, Coenzyme Q10, Ginkgo, Kava, Melatonin, Milk Thistle, Reishi, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Chlorpropamide: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Chlortetracycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Chlortetracycline + Demeclocycline + Tetracycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Chlorthalidone: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Chlorzoxazone: Garlic, St. John's Wort

Cholestyramine: Beta-Carotene, Calcium, Folic Acid, Iron, Magnesium, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

Choline Salicylate: Calcium, Omega-3 Fatty Acids, Policosanol, Vitamin K

Ciclosporin (Cyclosporine): Arginine, Echinacea, Ginkgo, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, St. John's Wort, Turmeric/Curcumin, Vitamin C, Vitamin E, Zinc

Cilazapril: Alpha-Lipoic Acid, Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Cilostazol: Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)

Cimetidine: Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Vitamin D, Zinc

Cinoxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Ciprofibrate: Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Ciprofloxacin: Calcium, Copper, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Cisatracurium: Magnesium

Cisplatin: Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Calcium, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Feverfew, Ginger, Ginkgo, Ginseng, Magnesium, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Potassium, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin B_6, Vitamin C, Vitamin E, Zinc

Citalopram: 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Cladribine: Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Clarithromycin: Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Clindamycin Oral: Licorice, Probiotic Flora, Vitamin K, Zinc

Clindamycin Topical: Zinc

Clobetasol: Aloe, Green Tea, Licorice, Vitamin C, Zinc

Clobetasol Topical (Clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Clobetasone: Aloe, Green Tea, Licorice, Vitamin C

Clocortolone: Aloe, Green Tea, Licorice, Vitamin C

Clocortolone Pivalate Topical (Clocortolone): Aloe, Green Tea, Licorice, Vitamin C

Clodronate: Calcium, Iron, Magnesium, Vitamin D, Zinc

Clofibrate: Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Iron, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Clomipramine: 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Clonazepam: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Clonidine: DHEA, Ephedra, Melatonin

Clonidine + Chlorthalidone: Arginine, Coenzyme Q10, DHEA, Ephedra, Melatonin, Potassium

Clopidogrel: Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)

Clorazepate: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Tryptophan, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Clotrimazole: Probiotic Flora, Vitamin B_2

Cloxacillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Clozapine: 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Selenium, Vitamin B_3, Vitamin B_6, Vitamin C

Co-Beneldopa (Levodopa + Benserazide): 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Cocaine: Ginseng

Codeine: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Codeine + Acetaminophen: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Colchicine: Beta-Carotene, Calcium, Folic Acid, Magnesium, Potassium, Vitamin A, Vitamin B_{12}

Colesevelam: Beta-Carotene, Calcium, Folic Acid, Iron, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

Colestipol: Beta-Carotene, Calcium, Folic Acid, Iron, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

Colestyramine (Cholestyramine): Beta-Carotene, Calcium, Folic Acid, Iron, Magnesium, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

Colistimethate: Licorice, Probiotic Flora, Vitamin K, Zinc

Conjugated Equine Estrogens: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Conjugated Equine Estrogens + Norgestrel: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Cortisone: Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Cortisone Eyedrops: Aloe, Green Tea, Licorice, Vitamin C

CPT-11 (Irinotecan): Aloe, Ginseng, Omega-3 Fatty Acids, Vitamin A, Vitamin C, Vitamin E

Cyclobenzaprine: Echinacea

Cycloheximide: Dang Gui, Echinacea

Cyclopenthiazide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Cyclopenthiazide + Oxprenolol: Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Cyclophosphamide: Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Carnitine, Echinacea, Eleuthero, Ginger, Ginseng, Licorice, Melatonin, Omega-3 Fatty Acids, Reishi, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

Cycloserine (CsA): Calcium, Folic Acid, Magnesium, Milk Thistle, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D

Cyclosporine: Arginine, Echinacea, Ginkgo, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, St. John's Wort, Turmeric/Curcumin, Vitamin C, Vitamin E, Zinc

Cyproterone: Black Cohosh, Vitamin D

Cytarabine: Echinacea, Eleuthero, Folic Acid, Ginseng, Vitamin B_1

D-Amphetamine (Dextroamphetamine): 5-HTP, Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B_6, Vitamin C, Zinc

D4T (Stavudine): Aloe, Carnitine, Coenzyme Q10, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

D600 (Gallopamil): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Dabigatran: Cayenne, DHEA, Policosanol

Dacarbazine (DTIC): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Dactinomycin: Echinacea, Eleuthero, Ginseng, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K

Dalteparin: Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Danaparoid: Cayenne, Chondroitin Sulfate, DHEA, Policosanol

Dapsone (DDS): Folic Acid, Licorice, PABA, Probiotic Flora, Vitamin E, Vitamin K, Zinc

Darbepoetin Alpha (Darbepoetin Alfa): Dang Gui, Iron, Vitamin B_6, Vitamin C

Darunavir: Copper, Garlic, St. John's Wort, Vitamin C

Daunorubicin: Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Ginseng, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Daunorubicin, Liposomal: Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Ginseng, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Debrisoquine: Ephedra

Deferasirox: Vitamin C

Delavirdine: St. John's Wort, Vitamin B_2

Delta-Aminolevulinic Acid (d-ALA): St. John's Wort

Demeclocycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Deprenyl (Selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

Desferoxamine: Copper, Iron, Vitamin C

Desflurane: Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Desiccated Thyroid (L-Thyroxine + L-Triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Desipramine: 5-HTP, Coenzyme Q10, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Desirudin: Cayenne, DHEA, Policosanol

Deslanoside: Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort

Desogestrel: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Desonide: Aloe, Green Tea, Licorice, Vitamin C

Desoximetasone: Aloe, Green Tea, Licorice, Vitamin C

Desoxymethasone: Aloe, Green Tea, Licorice, Vitamin C

Dexamethasone: Aloe, Calcium, Ephedra, Green Tea, Licorice, Vitamin C

Dexamethasone + Tobramycin: Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K

Dexamphetamine (Amphetamine + Dextroamphetamine): 5-HTP, Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B_6, Vitamin C, Zinc

Dextroamphetamine: 5-HTP, Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B6, Vitamin C, Zinc

Dextrothyroxine: Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Diaminodiphenylsulphone (Dapsone): Folic Acid, Licorice, PABA, Probiotic Flora, Vitamin E, Vitamin K, Zinc

Diazepam: Carnitine, DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Dichlorphenamide: Potassium

Diclofenac (Diclofenac Potassium; Diclofenac Sodium): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Diclofenac + Misoprostol: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Diclofenamide: Potassium

Dicloxacillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Dicumarol: Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Didanosine (ddI): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Dideoxycytidine (ddC): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Dideoxyinosine (Didanosine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Dienestrol: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Diflorasone: Aloe, Green Tea, Licorice, Vitamin C

Diflucortolone: Aloe, Green Tea, Licorice, Vitamin C

Diflunisal: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Policosanol, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin K, Zinc

Digitoxin: Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort

Digoxin: Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort, Vitamin D

Dihydroergotamine (DHE-45): 5-HTP, Tryptophan

Dihydrotachysterol: Vitamin D

Diltiazem: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Dimercaprol: Iron

Diphenylhydantoin: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Dipyridamole: Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Iron, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)

Dirithromycin: Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Disopyramide: Cascara, Magnesium, Potassium

Disulfiram: Vitamin C

Divalproex Semisodium/Sodium: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Selenium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

DMPS: Iron

DMSA: Iron

Dobutamine: Calcium

Docetaxel: Aloe, Beta-Carotene, Echinacea, Eleuthero, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin B_6, Vitamin C, Vitamin E

Docusate: Magnesium, Potassium

Dofetilide: Cascara, Magnesium, Potassium

Donepezil: Ginkgo

Dorzolamide: Potassium

Dorzolamide + Timolol: Potassium

Doxacurium: Magnesium

Doxazosin: Saw Palmetto, Vitamin B_3

Doxepin: 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Doxorubicin: Aloe, Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Ginseng, Green Tea, Hawthorn, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin B_2, Vitamin C, Vitamin D, Vitamin E

Doxorubicin, Pegylated Liposomal: Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin B_6, Vitamin E

Doxycycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Doxylamine: Vitamin B_6

Doxylamine + Pyridoxine: Vitamin B_6

Droperidol: Milk Thistle, Phenylalanine

Duloxetine: 5-HTP, Folic Acid, Ginkgo, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}

Dutasteride: Black Cohosh, Saw Palmetto

Dydrogesterone: Vitamin D, Vitex

Dyphylline: Potassium

Econazole: Echinacea

EDTA: Calcium, Copper, Iron, Vitamin C, Zinc

Efavirenz: St. John's Wort, Vitamin B_2

Eletriptan: 5-HTP, Feverfew, Tryptophan

Enalapril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Enalapril + Felodipine: Arginine, Calcium, Cayenne, Coenzyme Q10, Potassium, St. John's Wort, Zinc

Enalapril + Hydrochlorothiazide: Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Enflurane: Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Enoxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Enoxaparin: Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Entacapone: Folic Acid, Iron, *S*-Adenosylmethionine (SAMe), Vitamin B_6, Vitex

Ephedrine: Selenium

Ephedrine + Guaifenesin + Theophylline: Cayenne, Magnesium

Epinephrine: Magnesium, Potassium, Vitamin C

Epirubicin: Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Epo (Epoetin Alpha): Dang Gui, Iron, Vitamin B_6, Vitamin C

Epoetin Alpha/Epoetin Alfa (Erythropoietin): Dang Gui, Iron, Vitamin B_6, Vitamin C

Epoetin Beta: Dang Gui, Iron, Vitamin B_6, Vitamin C

Eprosartan: Alpha-Lipoic Acid, Potassium

Eptifibatide: Cayenne, Ginger, Policosanol, *S*-Adenosylmethionine (SAMe)

Ergotamine: 5-HTP, Tryptophan

Erythromycin + Benzoyl Peroxide: Vitamin E, Zinc

Erythromycin Oral: Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K, Zinc

Erythromycin Topical: Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Escitalopram: Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Esmolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Esomeprazole: Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc

Estazolam: DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3

Esterified Estrogens: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Esterified Estrogens + Methyltestosterone: Beta-Carotene, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin A, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol + Dydrogesterone: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol + Norethindrone (Oral): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol + Norethindrone Patch (Estradiol + Norethindrone Acetate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol + Norgestimate: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Cypionate: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Cypionate + Medroxyprogesterone Acetate: Beta-Carotene, Folic Acid, Magnesium, Vitamin A, Vitamin B_3, Vitamin D

Estradiol Hemihydrate: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Topical: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Transdermal: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Vaginal Ring: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Valerate: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Valerate + Cyproterone Acetate: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradiol Valerate + Norgestrel: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estrone: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estropipate: Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Eszopiclone: 5-HTP, Gotu Kola, Melatonin, Valerian

Etanercept: Echinacea

Ethacrynic Acid: Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc

Ethambutol: Copper, Folic Acid, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Zinc

Ethanol: Ginseng, Gotu Kola, Kava, Licorice, Milk Thistle, Turmeric/Curcumin

Ethinyl Estradiol: Arginine, Boron, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethinyl Estradiol + Desogestrel: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethinyl Estradiol + Ethynodiol: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethinyl Estradiol + Levonorgestrel: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethinyl Estradiol + Norethindrone: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethinyl Estradiol + Norethisterone (Ethinyl Estradiol + Norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethinyl Estradiol + Norgestrel: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethionamide: Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Ethosuximide: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Ethotoin: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Ethyl Biscoumacetate: Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Ethylphenacemide (Pheneturide): Calcium, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Ethynodiol: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Etidronate: Calcium, Iron, Magnesium, Vitamin D, Zinc

Etodolac: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Etonogestrel/Ethinyl Estradiol Vaginal Ring: Arginine, Copper, Dang Gui, Iron, Licorice, Magnesium, Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Zinc

Etoposide: Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort

Etretinate: Beta-Carotene, Calcium, Carnitine, Omega-3 Fatty Acids, Vitamin A, Vitamin E

Etrorelix: Black Cohosh

Exemestane: Green Tea

Ezetimibe: Policosanol

Famciclovir: Astragalus

Famotidine: Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc

Felbamate: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Felodipine: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Felodipine + Ramipril: Arginine, Calcium, Coenzyme Q10, Magnesium, Potassium, St. John's Wort

Fenofibrate: Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Zinc

Fenoprofen: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Fenoterol: Calcium, Magnesium, Potassium

Fentanyl: Ephedra, Ginger, Ginseng, Gotu Kola, Magnesium, Phenylalanine, Tyrosine

Fexofenadine: St. John's Wort

Filgrastim: Echinacea

Finasteride: Black Cohosh, Saw Palmetto

Flecainide: Cascara, Magnesium, Potassium

Floxuridine: Echinacea, Eleuthero, Folic Acid, Vitamin B_3

Fluconazole: Echinacea, St. John's Wort

Fludarabine: Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Fludestrin (Testolactone): Beta-Carotene, DHEA, Vitamin A, Zinc

Fludroxycortide: Aloe, Green Tea, Licorice, Vitamin C

Fluocinonide: Aloe, Green Tea, Licorice, Vitamin C

Fluocortolone: Aloe, Green Tea, Licorice, Vitamin C

Fluorouracil (5-FU): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginkgo, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Fluoxetine: 5-HTP, Chromium, DHEA, Folic Acid, Ginkgo, Inositol, Melatonin, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Fluoxymesterone: DHEA, Echinacea, Zinc

Fluphenazine: Chromium, Coenzyme Q10, Ginkgo, Kava, Melatonin, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Flurandrenolide: Aloe, Green Tea, Licorice, Vitamin C

Flurazepam: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Flurbiprofen: Vitamin D

Flutamide: Black Cohosh, Vitamin D

Fluticasone: Aloe, Green Tea, Licorice, Vitamin C

Fluvastatin: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Fluvoxamine: 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Melatonin, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Folic Acid: Zinc

Fondaparinux: Cayenne, Chondroitin Sulfate, DHEA, Policosanol

Formoterol: Calcium, Magnesium, Potassium

Fosamprenavir: Copper, Garlic, St. John's Wort, Vitamin C

Foscarnet: Magnesium

Fosinopril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Fosphentyoin: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Frovatriptan: 5-HTP, Feverfew, Tryptophan

Fujimycin (Tacrolimus): Echinacea, St. John's Wort

Furaltadone: Licorice, Probiotic Flora, Vitamin K, Zinc

Furazolidone: Licorice, Probiotic Flora, Vitamin K, Zinc

Furbiprofen: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium,

Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Furosemide: Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc

G-Strophanthin (Ouabain): Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort

Gabapentin: Carnitine, Folic Acid, Vitamin B_3, Vitamin B_6, Vitamin D

Gallopamil: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Ganciclovir: Astragalus

Ganirelix: Black Cohosh

Gatifloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

GCSF: Echinacea

Gemcitabine: Aloe, Echinacea, Eleuthero, Folic Acid, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin C, Vitamin E

Gemfibrozil: Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Gentamicin: Alpha-Lipoic Acid, Calcium, Carnitine, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitamin K

Glibenclamide (Glyburide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Glimepiride: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Glipizide: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Glipizide + Metformin: Aloe, Alpha-Lipoic Acid, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Glyburide: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Glyburide + Metformin: Aloe, Alpha-Lipoic Acid, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Glycerin-Containing Suppositories: Potassium

Glyceryl Trinitrate (Nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

GMCSF: Echinacea

Goserelin: Black Cohosh, Vitamin D

Griseofulvin: Echinacea, Vitamin B_3, Vitamin E

GTN (Nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Guaifenesin + Phenylpropanolamine: Potassium, Tyrosine

Guanadrel: Ephedra

Guanethidine: Ephedra, Vitamin B_3

Halcinonide: Aloe, Green Tea, Licorice, Vitamin C

Halobetasol: Aloe, Green Tea, Licorice, Vitamin C

Haloperidol: Alpha-Lipoic Acid, Chromium, Ginkgo, Iron, Kava, Melatonin, Milk Thistle, Phenylalanine, Potassium, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Halothane: Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Heparin: Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C, Vitamin D

Heparin + Phosphatidylcholine + Aescin: Horse Chestnut

Heparin, Unfractionated: Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Hirudin: Cayenne, DHEA, Policosanol

Hizaricin (Cycloheximide): Dang Gui, Echinacea

Hydralazine: Melatonin, Vitamin B_6, Zinc

Hydralazine + Hydrochlorothiazide: Arginine, Coenzyme Q10, Melatonin, Potassium, Vitamin B_6

Hydrochlorothiazide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Hydrocodone: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Hydrocodone + Acetaminophen: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Hydrocodone + Acetylsalicylic Acid: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Hydrocodone + Ibuprofen: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Ginseng, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_2, Vitamin B_6, Vitamin C, Zinc

Hydrocortisone: Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Hydrocortisone 17-Butyrate/Acetate/Probutate/Valerate: Aloe, Green Tea, Licorice, Vitamin C

Hydroflumethiazide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Hydrogel Dressings: Aloe

Hydromorphone: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Hydroxychloroquine: Calcium, Magnesium, Vitamin B_2, Vitamin B_6, Vitamin D

Hyoscine Hydrobromide: Ginger

Hyoscyamine: Iron

Ibandronate: Calcium, Iron, Magnesium, Vitamin D, Zinc

Ibuprofen: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Ibuprofen + Hydrocodone: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Ibutilide: Cascara, Magnesium, Potassium

Idarubicin: Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Ifosfamide: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Imatinib: St. John's Wort

Imidazole Carboxamide (Dacarbazine): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Imipenem: Ginseng, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Imipenem + Cilastatin: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Imipramine: 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Indapamide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Indinavir: Copper, Garlic, St. John's Wort, Vitamin C

Indomethacin: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin A, Vitamin B_2, Vitamin B_6, Vitamin C, Zinc

Infliximab: Echinacea

Influenza Vaccine: Ginseng

Insulin: Alpha-Lipoic Acid, Bilberry, Chromium, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Licorice, Magnesium, Milk Thistle, Omega-3 Fatty Acids, Potassium, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Interferon Alpha: Astragalus, Echinacea, Iron, Licorice, Zinc

Interferon Gamma-1b: Echinacea

Intrauterine L-Norgestrel System: Vitamin D

Ipecac: Potassium

Irbesartan: Alpha-Lipoic Acid, Potassium

Irbesartan + Hydrochlorothiazide: Alpha-Lipoic Acid, Potassium

Irinotecan: Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

Iron Salts (Nonheme Iron): Green Tea

Isocarboxazid: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Isoetharine: Calcium, Magnesium, Potassium

Isoflurane: Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Isoniazid (Isonicotinic Acid Hydrazide): Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E

Isoniazid + Pyrazinamide + Rifampicin: Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E

Isoniazid + Rifampicin: Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E

Isoproterenol: Garlic

Isosorbide Dinitrate: Arginine, Carnitine, Folic Acid, Vitamin C

Isosorbide Dinitrate + Hydralazine: Arginine, Carnitine, Folic Acid, Melatonin, Vitamin B_6, Vitamin C

Isosorbide Mononitrate: Arginine, Carnitine, Folic Acid, Vitamin C

Isotretinoin (13-*cis* Retinoic Acid): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Isradipine: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Itraconazole: Echinacea, St. John's Wort

Kaken (Cycloheximide): Dang Gui, Echinacea

Kanamycin: Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K

Kaolin Clay: Ephedra

Ketoconazole: Black Cohosh, Echinacea, Green Tea, Vitamin D

Ketoprofen: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Ketorolac: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

L-Deprenyl/L-Deprenil (Selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

L-Norgestrel (Norgestrel, Oral): Magnesium, St. John's Wort

L-Thyroxine + L-Triiodothyronine: Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

L-Triiodothyronine: Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Labetalol: Potassium

Lactulose: Potassium

Lamivudine: Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Lamivudine + Zidovudine: Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc

Lansoprazole: Beta-Carotene, Calcium, Chromium, Iron, Kava, Probiotic Flora, St. John's Wort, Vitamin B_{12}, Zinc

Lansoprazole + Amoxicillin + Clarithromycin: Licorice, Probiotic Flora, Vitamin C, Vitamin K, Zinc

Lepirudin: Cayenne, DHEA, Policosanol

Lercanidipine: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Letrozole: Green Tea

Leuprolide: Black Cohosh, Vitamin D

Leurocristine (Vincristine): Alpha-Lipoic Acid, Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin

Levalbuterol: Calcium, Magnesium, Potassium

Levamisole: Beta-Carotene, Echinacea, Vitamin A

Levetiracetam: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Levodopa: Folic Acid, Iron, Kava, Methionine, Phenylalanine, Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C

Levodopa + Benserazide: 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Levodopa + Carbidopa: 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Levodopa + Carbidopa + Entacapone: 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_6, Vitamin C, Vitex

Levofloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Levomepromazine (Methotrimeprazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Levonorgestrel, Implant: Magnesium, St. John's Wort

Levonorgestrel, Oral Postcoital Contraceptive: Magnesium, St. John's Wort

Levorphanol: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Levothyroxine (Levoxin): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Lincomycin: Licorice, Probiotic Flora, Vitamin K, Zinc

Lindane: Vitamin E

Linezolid: Licorice, Probiotic Flora, Vitamin K, Zinc

Liothyronine Sodium (L-Triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Liothyronine Sodium (Synthetic T_3) (L-Triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Liotrix (L-Thyroxine + L-Triiodothyronine [Synthetic]): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Liquid Parafin (Mineral Oil): Beta-Carotene, Calcium, Potassium, Vitamin A, Vitamin D, Vitamin E, Vitamin K

Lisinopril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Lisinopril + Hydrochlorothiazide: Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Lithium Carbonate: 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Lomefloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Lometrexol (T64): Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Loperamide: St. John's Wort

Lopinavir + Ritonavir: Copper, Garlic, St. John's Wort, Vitamin C

Loracarbef: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Lorazepam: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Losartan: Alpha-Lipoic Acid, Potassium

Losartan + Hydrochlorothiazide: Alpha-Lipoic Acid, Arginine, Calcium, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Lovastatin: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Lovastatin + Niacin: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Magnesium Hydroxide: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc

Magnesium Salicylate: Calcium, Omega-3 Fatty Acids, Policosanol, Vitamin K

Magnesium Trisilicate: Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc

Magnesium-containing Products: Potassium

Mecamylamine: Vitamin B_3

Mecamylamine Hydrochloride (Mecamylamine): Vitamin B_3

Mechlorethamine: Astragalus, Carnitine, Echinacea, Eleuthero, Ginger, Selenium, Turmeric/Curcumin

Meclofenamate: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Medazepam: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Medroxyprogesterone: Vitamin D

Medroxyprogesterone + Conjugated Estrogens (Medroxyprogesterone Conjugated Equine Estrogens): Arginine, Beta-Carotene, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin A, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Medroxyprogesterone, Injection: Beta-Carotene, Calcium, Folic Acid, Vitamin A, Vitamin B_3, Vitamin D

Medroxyprogesterone, Oral: Beta-Carotene, Calcium, Folic Acid, Magnesium, St. John's Wort, Vitamin A, Vitamin D

Mefenamic Acid: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Meloxicam: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Melperon: Milk Thistle, Phenylalanine

Melphalan: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Meperidine: Chromium, Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Mephenytoin: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Mephobarbital: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Mercaptopurine (6-MP): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_3
Meropenem: Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Mesalamine (Mesalazine): Vitamin B_{12}
Mesoridazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Mestranol + Norethindrone: Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc
Metaproterenol: Calcium, Magnesium, Potassium
Metformin: Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}
Methadone: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Methamphetamine: Ginseng
Methandrostenolone (Methandienone): Echinacea, Milk Thistle
Methazolamide: Potassium
Methenolone Enanthate: Echinacea
Methicillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Methohexital: DHEA, Gotu Kola, Valerian, Vitamin B_2
Methotrexate (MTX): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginseng, Iron, Melatonin, Milk Thistle, Omega-3 Fatty Acids, PABA, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E
Methotrimeprazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Methoxamine: Melatonin
Methsuximide: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Methyclothiazide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc
Methylcellulose: Potassium, Vitamin B_2
Methyldopa: Ephedra, Iron, Vitamin B_{12}
Methyldopa + Chlorothiazide: Arginine, Coenzyme Q10, Ephedra, Potassium, Vitamin B_{12}
Methyldopa + Hydrochlorothiazide: Arginine, Coenzyme Q10, Ephedra, Potassium, Vitamin B_{12}
Methylphenidate: 5-HTP, Iron, Reishi, Tyrosine, Zinc
Methylprednisolone: Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Methyltestosterone: Beta-Carotene, DHEA, Vitamin A, Zinc
Metoclopramide: Vitamin B_2, Zinc
Metocurine Iodide: Magnesium
Metolazone: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc
Metoprolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Metoprolol + Hydrochlorothiazide: Arginine, Calcium, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Policosanol, Potassium, Vitamin C, Vitamin D, Zinc
Metronidazole (Systemic): Licorice, Milk Thistle, Probiotic Flora, Vitamin K, Zinc
Metronidazole (Vaginal): Zinc
Mexiletine: Cascara, Magnesium, Potassium, Vitamin C
Mezlocillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Midazolam: DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3
Mineral Oil: Beta-Carotene, Calcium, Potassium, Vitamin A, Vitamin D, Vitamin E, Vitamin K
Minocycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Mipobroman: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Mirtazapine: Melatonin
Misoprostol: Magnesium
Mitomycin: Echinacea, Eleuthero, Ginseng, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K
Mitoxantrone: Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E
Mivacurium: Magnesium
Moclobemide: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6
Modafinil: Reishi, Tyrosine
Moexipril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc
Monobasic Sodium Phosphate Monohydrate + Dibasic Sodium Phosphate Heptahydrate: Potassium
Monomycin (Paromomycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Morphine: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Morphine Hydrochloride + Codeine Hydrochloride + Papaverine Hydrochloride: Ephedra, Ginger, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Morphine Sulfate (Morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Moxifloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Mycophenolate: Echinacea, Magnesium, Turmeric/Curcumin
Nabumetone: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Nadolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Nadroparin: Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Nafcillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Nalidixic Acid: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Naloxone: Phenylalanine
Nandrolone: Echinacea
Naproxen: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Naramycin, Naramycin A (Cycloheximide): Dang Gui, Echinacea
Naratriptan: 5-HTP, Feverfew, Tryptophan
Nateglinide: Chromium, Vitamin B_3
Nebivolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Nefazodone: St. John's Wort
Nelfinavir: Copper, Garlic, St. John's Wort, Vitamin C
Neocycloheximide (Cycloheximide): Dang Gui, Echinacea
Neomycin: Alpha-Lipoic Acid, Beta-Carotene, Calcium, Eleuthero, Folic Acid, Ginger, Ginkgo, Horse Chestnut, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin D, Vitamin K
NET EN (Norethindrone, Injectable): Magnesium, St. John's Wort, Vitamin B_3
Netilmicin: Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Nevirapine: St. John's Wort, Vitamin B_2
Niacin: Chromium, Omega-3 Fatty Acids
Nicardipine: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Nicotine Transdermal Patches: Vitamin B_3
Nicoumalone: Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_5, Vitamin C, Vitamin E, Vitamin K, Zinc
Nifedipine: Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Nilutamide: Black Cohosh, Vitamin D
Nimodipine: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Nisoldipine: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Nitrendipine: Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Nitrofurantoin: Licorice, Magnesium, Probiotic Flora, Vitamin B_6, Vitamin K, Zinc
Nitrofurazone: Licorice, Probiotic Flora, Vitamin K, Zinc
Nitrogen Mustard (Mechlorethamine): Astragalus, Carnitine, Echinacea, Eleuthero, Ginger, Selenium, Turmeric/Curcumin
Nitroglycerin: Arginine, Carnitine, Folic Acid, Vitamin C
Nitrous Oxide: Folic Acid, Vitamin B_{12}
Nizatidine: Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc
Nor-Testosterone (Nandrolone): Echinacea
Nordihydroguaiaretic Acid (NDGA): Vitamin A
Norethindrone: Vitamin D, Vitex
Norethindrone, Oral: Magnesium, St. John's Wort
Norethisterone: Magnesium, St. John's Wort, Vitamin D
Norethisterone Enanthate (Norethindrone, Injectable): Magnesium, St. John's Wort, Vitamin B_3, Vitex
Norethisterone Enanthate + Estradiol Valerate: Magnesium, Vitamin B_3
Norfloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Norgestrel, Oral: Magnesium, St. John's Wort
Nortriptyline: 5-HTP, Coenzyme Q10, Milk Thistle, S-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Nystatin: Echinacea, Zinc
Nystatin, Topical: Echinacea
Ofloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Olanzapine: 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Olestra: Vitamin K
Olmesartan: Alpha-Lipoic Acid, Potassium
Omeprazole: Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Vitamin E, Zinc
Opium and Belladonna: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Opium Tincture: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Opium, Camphor, Anise, Benzoic Acid, and Glycerin (Paregoric): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Oprelevkin: Echinacea
Orfloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Orlistat: Beta-Carotene, Coenzyme Q10, Vitamin A, Vitamin D, Vitamin E, Vitamin K
Ornidazole: Milk Thistle
Ouabain: Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort
Oxacillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Oxaliplatin: Alpha-Lipoic Acid, Astragalus, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Ginger, Ginkgo, Ginseng, Milk Thistle, Selenium, St. John's Wort, Vitamin E
Oxandrolone: Echinacea
Oxaprozin: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Oxazepam: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3
Oxcarbazepine (Oxycarbamazepine): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Oxprenolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Oxprenolol + Cyclopenthiazide: Arginine, Calcium, Coenzyme Q10, Potassium

Oxtriphylline: Potassium

Oxycodone: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Oxycodone + Acetaminophen: Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Oxycodone + Acetylsalicylic Acid: Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Oxymetholone: Echinacea

Oxymorphone: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Oxytetracycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Oxytocin: Ephedra

***p*-Aminosalicylic Acid (Para-Aminosalicylic Acid):** Vitamin B_{12}

Paclitaxel: Aloe, Beta-Carotene, Echinacea, Eleuthero, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, PABA, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

Paclitaxel, Protein-Bound: Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin

Pamidronate: Calcium, Iron, Magnesium, Vitamin D, Zinc

Pancreatic Enzymes (Pancreatin): Folic Acid

Pancuronium: Magnesium

Pantoprazole: Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc

Para-Aminosalicylic Acid (4-Aminosalicylic Acid): Vitamin B_{12}

Paregoric: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Pargyline: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_3

Paromomycin: Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K

Paroxetine: 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

PAS (Para-Aminosalicylic Acid): Vitamin B_{12}

Pegfilgastin: Echinacea

Pegylated Interferon Alpha-2b: Echinacea

Pegylated Liposomal Doxorubicin (Doxorubicin, Pegylated Liposomal): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin B_6, Vitamin E

Pemetrexed: Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_{12}

Pemetrexed + Cisplatin: Vitamin B_{12}

Pemoline: Reishi, Tyrosine

Penbutolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Penicillamine: Copper, Iron, Magnesium, Vitamin B_6, Zinc

Penicillin G (Benzathine Penicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Penicillin V (Pen VK): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Pentamidine: Magnesium

Pentazocine: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Pentobarbital: Calcium, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Pentostatin: Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Pentoxifylline: Arginine, Cayenne, Coenzyme Q10, Policosanol, Vitamin E

Pericyazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Perindopril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Perphenazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Phenelzine: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Pheneturide: Calcium, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Phenformin: Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Phenindione: Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B3, Vitamin C, Vitamin E, Vitamin K, Zinc

Phenobarbital (Phenobarbitone): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Reishi, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Phenprocoumon: Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Phensuximide: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Phenylalanine Mustard: Astragalus, Carnitine, Echinacea, Eleuthero, Ginger, Selenium

Phenylethylamine: Phenylalanine

Phenylpropanolamine: Potassium, Tyrosine
Phenylpropanolamine + Guaifenesin: Potassium, Tryosine
Phenytoin: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Pindolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Pioglitazone: Chromium, Vitamin B_3
Pipecuronium: Magnesium
Piperacillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Piperacillin + Tazobactam: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Pipobroman: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Piracetam: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Pirbuterol: Calcium, Magnesium, Potassium
Piroxicam: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Pivampicillin: Carnitine
Pivanex: Carnitine
Pivmecillinam: Carnitine
***Plantago isphagula/ovata/psyllium* (Psyllium):** Potassium, Vitamin B_2
***Plantago* Seed Mucilage (Psyllium):** Potassium, Vitamin B_2
Plicamycin: Ginseng

Prochlorperazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Progesterone, Micronized: Vitamin D
Progestin(s)/Progestogen(s): Beta-Carotene, Calcium, Folic Acid, Magnesium, St. John's Wort, Vitamin A, Vitamin D
Promethazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Propiomazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Propoxyphene: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Propoxyphene + Acetaminophen: Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Propranolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Policosanol, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E
Propranolol + Bendrofluazide: Arginine, Calcium, Coenzyme Q10, Policosanol, Potassium, Vitamin C
Proteolytic Enzymes: Folic Acid
Protriptyline: 5-HTP, Coenzyme Q10, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Pseudoephedrine: Potassium
Psyllium Husk (Psyllium): Potassium, Vitamin B_2
Purgoxin (Digoxin): Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort, Vitamin D
Pyrazinamide (PZA): Folic Acid, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D
Pyrimethamine: Folic Acid, Iron
PZA: See *Pyrazinamide*.
Quazepam: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3
Quetiapine: 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C
Quinacrine: Vitamin B_2
Quinapril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc
Quinethazone: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc
Quinidine: Beta-Carotene, Cascara, Magnesium, Potassium
Rabeprazole: Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc
Radiotherapy: Coenzyme Q10, Eleuthero, Ginseng, Melatonin, Vitamin B_3, Zinc; see also *Chemotherapy and Radiotherapy* in Drug Class Cross-Index.
Raloxifene: Black Cohosh, Dang Gui, Green Tea, Vitamin D
Raltitrexed (ZD-1694): Echinacea, Eleuthero, Folic Acid, Vitamin B_1
Ramipril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Ranitidine: Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc
Ranitidine + Bismuth + Citrate: Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc
Rasagiline: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine
Recombinant Erythropoietin (Epoetin Alpha): Dang Gui, Iron, Vitamin B_6, Vitamin C
Repaglinide: Chromium, Vitamin B_3
Reserpine: Ephedra, Reishi
Reteplase, Recombinant: Astragalus
Ribavirin: *S*-Adenosylmethionine (SAMe)
Ribavirin + Interferon Alpha-2b: Iron, Licorice, Zinc
Rifampicin: Folic Acid, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E
Rimiterol: Calcium, Magnesium, Potassium
Risedronate: Calcium, Iron, Magnesium, Vitamin D, Zinc
Risperidone: 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E
Ritonavir: Copper, Garlic, St. John's Wort, Vitamin C
Rizatriptan: 5-HTP, Feverfew, Tryptophan
Rocuronium: Magnesium
Rofecoxib: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin C, Zinc
Rosiglitazone: Chromium, Vitamin B_3
Rosuvastatin: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E
Salazosulfapyridine (Sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Salbutamol: Calcium, Magnesium, Potassium
Salicylazosulfapyridine (Sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Salicylic Acid (Salsalate): Calcium, Folic Acid, Omega-3 Fatty Acids, Policosanol, Vitamin C, Vitamin K, Zinc
Salicylsalicylic Acid (Acetylsalicylic Acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Salmeterol: Calcium, Magnesium, Potassium
Salsalate: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Policosanol, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin K, Zinc
Saquinavir: Copper, Garlic, St. John's Wort, Vitamin C
Saquinavir + Ritonavir (SQV/RTV): Copper, Garlic, St. John's Wort, Vitamin C
Sargramostim: Echinacea
Scoline (Suxamethonium): Ginger, Magnesium
Scopolamine: Dang Gui, Vitamin B_1
Secale Alkaloids: Ephedra
Secnidazole: Milk Thistle
Secobarbital: DHEA, Gotu Kola, Valerian, Vitamin B_2
Selegiline: 5-HTP, Cayenne, Chromium, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex
Senna: Potassium
Sertraline: Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc
Sevoflurane: Aloe, Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian
Sibutramine: 5-HTP, Tryptophan
Sildenafil: Arginine
Silver Sulfadiazine: Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Simvastatin: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin B_{12}, Vitamin C, Vitamin E
Simvastatin + Extended-Release Nicotinic Acid: Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E
Sodium Bicarbonate: Ephedra
Sodium Fluoride: Calcium, Vitamin D
Sodium Polystyrene Sulfonate: Magnesium
Sodium Salicylate: Calcium, Omega-3 Fatty Acids, Policosanol, Vitamin K
Sodium Sulfacetamide: Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Sodium Thiosalicylate: Calcium, Omega-3 Fatty Acids, Policosanol, Vitamin K
Sodium Valproate: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Sotalol: Calcium, Carnitine, Cascara, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Sparfloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Spironolactone: Arginine, Calcium, Folic Acid, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Zinc
Spironolactone + Hydrochlorothiazide: Arginine, Calcium, Coenzyme Q10, Folic Acid, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Stanozolol: Echinacea, Iron
Staphcillin (Methicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Stavudine: Aloe, Carnitine, Coenzyme Q10, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc
Streptokinase: Astragalus
Streptomycin: Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin K
Streptozocin: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Succinylcholine (Suxamethonium): Ginger, Magnesium
Sucralfate: Calcium, Vitamin D
Sulfadoxine: Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Sulfadoxine + Pyrimethamine: Folic Acid, Iron, Vitamin B_2
Sulfaguanidine: Ginger
Sulfamethoxazole: Calcium, Folic Acid, Licorice, Magnesium, PABA, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Sulfanilamide: Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Sulfasalazine (Sulphasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Sulfinpyrazone: Vitamin B_2, Vitamin B_3
Sulfisoxazole: Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Sulindac: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Sumatriptan: 5-HTP, Feverfew, Tryptophan
Surgery: Aloe, Garlic
Suxamethonium: Ginger, Magnesium
T_3 (L-Triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
T_4 (Levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
T_4 + T_3 (L-Thyroxine + L-Triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
Tacrine: Echinacea, Melatonin, Milk Thistle, Vitamin C
Tacrolimus (FK-506): Echinacea, St. John's Wort
Tadalafil: Arginine
Tamoxifen: Aloe, Black Cohosh, Calcium, Dang Gui, Feverfew, Ginseng, Green Tea, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin C, Vitamin E
Tamsulosin: Saw Palmetto, Vitamin B_3
Telmisartan: Alpha-Lipoic Acid, Potassium
Temazepam: DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3
Temozolomide: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Teniposide: St. John's Wort
Tenofovir: Aloe, Carnitine, Coenzyme Q10, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc
Terazosin: Saw Palmetto, Vitamin B_3
Terbutaline: Potassium
Testolactone (Testolacton): Beta-Carotene, DHEA, Vitamin A, Zinc
Testosterone Cypionate (Methyltestosterone): Beta-Carotene, DHEA, Vitamin A, Zinc
Testosterone Undecanoate (Testosterone): Beta-Carotene, DHEA, Zinc
Tetracycline: Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Tetrathiomolybdate: Copper, Zinc
Theophylline: Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6
Thiethylperazine: Milk Thistle
Thioguanine (6-TG): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_3
Thiopental: DHEA, Gotu Kola, Valerian, Vitamin B_2
Thiopentone: DHEA, Ginger, Gotu Kola, Valerian, Vitamin B_2
Thioproperazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Thioridazine: Coenzyme Q10, Milk Thistle, Potassium, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin D
Thiotepa: Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Thyroxine (Levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
Tiagabine: Carnitine, Folic Acid, Vitamin B_3
Ticarcillin: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Ticarcillin + Clavulanic Acid: Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Ticlopidine: Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)
Tiludronate: Calcium, Iron, Magnesium, Vitamin D, Zinc
Timolol: Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Tinidazole: Milk Thistle
Tinzaparin: Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C
Tipranavir: Copper, Garlic, St. John's Wort, Vitamin C
Tirofiban: Cayenne, Ginger, Policosanol, *S*-Adenosylmethionine (SAMe)
TMC114 (Darunavir): Copper, Garlic, St. John's Wort, Vitamin C
Tobramycin: Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Tobramycin and Dexamethasone Ophthalmic Ointment (Dexamethasone + Tobramycin): Alpha-Lipoac Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Tolazamide: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3
Tolbutamide: Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3
Tolmetin: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Topiramate: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Potassium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Topotecan: Feverfew
Toremifene: Black Cohosh, Dang Gui, Green Tea

Torsemide: Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc
Trandolapril: Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc
Trandolapril + Verapamil: Arginine, Calcium, Coenzyme Q10, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin E
Tranylcypromine: 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Melatonin, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6
Trastuzumab: Cascara, Green Tea
Trazodone: 5-HTP, Ginkgo, St. John's Wort
Trenbolone: Echinacea
Tretinoin: Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E
Triamcinolone + Nystatin: Licorice
Triamcinolone, Oral: Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Green Tea, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Triamcinolone, Topical: Aloe, Calcium, Green Tea, Licorice, Vitamin C
Triamterene: Arginine, Calcium, Folic Acid, Glucosamine Sulfate, Magnesium, Potassium, Zinc
Triamterene + Hydrochlorothiazide: Arginine, Calcium, Coenzyme Q10, Folic Acid, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Triazolam: DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3
Trichlormethiazide: Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc
Trientine (Trien): Copper, Iron
Trienthylene Tetramine: Copper, Iron
Trifluoperazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Triflupromazine: Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Trimethadione: Carnitine, Folic Acid
Trimethaphan: Vitamin B_3
Trimethoprim: Folic Acid, Licorice, Probiotic Flora, Vitamin B_2, Vitamin K, Zinc
Trimethoprim-Sulfamethoxazole: Calcium, Folic Acid, Licorice, Magnesium, PABA, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin C, Vitamin K, Zinc
Trimipramine: 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, Potassium, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Triperidol: Milk Thistle, Phenylalanine
Triple Sulfa: Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Triptorelin: Black Cohosh, Melatonin, Vitamin D
Troleandomycin: Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Trovafloxacin: Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Tubocurarine: Magnesium
Tulobuterol: Calcium, Magnesium, Potassium
Tumor Necrosis Factor Alpha (TNF-α): Melatonin, Omega-3 Fatty Acids
UFH (Heparin, Unfractionated): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D
Uracil Mustard: Astragalus, Carnitine, Echinacea, Eleuthero, Ginger, Selenium
Uramustine (Uracil Mustard): Astragalus, Carnitine, Echinacea, Eleuthero, Ginger, Selenium
Urokinase: Astragalus
Ursodeoxycholic Acid (UDCA): *S*-Adenosylmethionine (SAMe), Vitamin B_3
Valciclovir: Astragalus
Valdecoxib: Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin C, Zinc
Valproate Semisodium/Valproate Sodium: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Selenium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Valproic Acid (Valproate): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Selenium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Valsartan: Alpha-Lipoic Acid, Potassium
Valsartan + Hydrochlorothiazide: Alpha-Lipoic Acid, Potassium
Vancomycin: Licorice, Probiotic Flora, Vitamin K, Zinc
Vardenafil: Arginine
Vecuronium: Ginger, Magnesium
Venlafaxine: 5-HTP, Folic Acid, Ginkgo, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}
Verapamil: Calcium, Carnitine, Folic Acid, Magnesium, Melatonin, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E
Vidarabine: Methionine, Reishi, *S*-Adenosylmethionine (SAMe)
Vigabatrin: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Vinblastine: Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin
Vincristine: Alpha-Lipoic Acid, Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin
Vincristine + Dactinomycin + Cyclophosphamide: Feverfew
Vinorelbine: Echinacea, Eleuthero, St. John's Wort
Voriconazole: Echinacea, St. John's Wort
Warfarin: Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Echinacea, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Iron, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Zinc
Zafirlukast: Melatonin
Zalcitabine (Dideoxycytidine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Zaleplon: Gotu Kola, Melatonin, Valerian
Zidovudine (AZT, ZDV): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc
Zidovudine + Lamivudine (AZT + 3TC): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc
Ziprasidone: 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C
Zoledronic Acid (Zoledronate): Calcium, Iron, Magnesium, Vitamin D, Zinc
Zolmitriptan: 5-HTP, Feverfew, Tryptophan
Zolpidem: 5-HTP, Gotu Kola, Melatonin, Valerian
Zonisamide: Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Potassium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

3TC (lamivudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc
A-Spas S/L (hyoscyamine): Iron
A/T/S (erythromycin topical): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Abbokinase (urokinase): Astragalus
Abbokinase Open-Cath (urokinase): Astragalus
Abilify (aripiprazole): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C
Abilitat (aripiprazole): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C
Abraxane (paclitaxel, protein-bound): Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin
Accolate (zafirlukast): Melatonin
Accolcit (zafirlukast): Melatonin
Accupril (quinapril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc
Accutane (isotretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E
Aceon (perindopril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc
Acezide (captopril + hydrochlorothiazide): Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Achromycin (tetracycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
AcipHex (rabeprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc
Acitrom (nicoumalone): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Aclovate (alclometasone): Aloe, Green Tea, Licorice, Vitamin C
Acti-Aid (cycloheximide): Dang Gui, Echinacea
Acticort 100 (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
ActiDione (cycloheximide): Dang Gui, Echinacea
Actigall (ursodeoxycholic acid): *S*-Adenosylmethionine (SAMe), Vitamin B_3
Actimmune (interferon gamma-1b): Echinacea
Actin-N (nitrofurazone): Licorice, Probiotic Flora, Vitamin K, Zinc
Actiq Oral Transmucosal (fentanyl): Ephedra, Ginger, Ginseng, Gotu Kola, Magnesium, Phenylalanine, Tyrosine
Actisite (tetracycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Actispray (cycloheximide): Dang Gui, Echinacea
Activase (alteplase, recombinant, parenteral): Astragalus
Activella (estradiol + norethindrone [oral]): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Actonel (risedronate): Calcium, Iron, Magnesium, Vitamin D, Zinc
Actos (pioglitazone): Chromium, Vitamin B_3
Acular ophthalmic (ketorolac): Vitamin B_6
Acutrim (phenylpropanolamine): Potassium, Tyrosine
Aczone (dapsone): Folic Acid, Licorice, PABA, Probiotic Flora, Vitamin E, Vitamin K, Zinc
Adalat LA (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Adalat Retard (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Adalat (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Adapin (doxepin): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Adcomag trisil (magnesium trisilicate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc
Adderall (amphetamine + dextroamphetamine): 5-HTP, Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B_6, Vitamin C, Zinc
Adipine MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Adrenalin (epinephrine): Magnesium, Potassium, Vitamin C
Adrenalin Chloride Solution, injectable (epinephrine): Magnesium, Potassium, Vitamin C
Adrenaline, Epi (epinephrine): Magnesium, Potassium, Vitamin C
Adriamycin (doxorubicin): Aloe, Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Ginseng, Green Tea, Hawthorn, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin B_2, Vitamin C, Vitamin D, Vitamin E
Adrucil (fluorouracil): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginkgo, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E
Advanced Formula Di-Gel Tablets (calcium carbonate + magnesium hydroxide + simethicone): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc
Advicor (lovastatin + niacin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E
Advil (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Aeroseb-Dex (dexamethasone): Aloe, Calcium, Ephedra, Green Tea, Licorice, Vitamin C

Aceroseb-HC (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Afrinol (pseudoephedrine): Potassium
Agenerase (amprenavir): Copper, Garlic, St. John's Wort, Vitamin C
Aggrastat (tirofiban): Cayenne, Ginger, Policosanol, *S*-Adenosylmethionine (SAMe)
Aggrenox (acetylsalicylic acid + dipyridamole [extended-release]): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Agoral (mineral oil): Beta-Carotene, Calcium, Potassium, Vitamin A, Vitamin D, Vitamin E, Vitamin K
Agrylin (anagrelide)
Airomir (salbutamol): Potassium
AK-Sulf (sodium sulfacetamide): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Akne-Mycin (erythromycin topical): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
AKTob (tobramycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Ala-Cort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Ala-Scalp HP (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Albuterol Inhaled (albuterol): Calcium, Magnesium, Potassium
Aldactazide (spironolactone + hydrochlorothiazide): Arginine, Calcium, Coenzyme Q10, Folic Acid, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Aldactone (spironolactone): Arginine, Calcium, Folic Acid, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Zinc
Aldoclor (methyldopa + chlorothiazide): Arginine, Coenzyme Q10, Ephedra, Potassium, Vitamin B_{12}
Aldomet (methyldopa): Ephedra, Iron, Vitamin B_{12}
Aldoril (methyldopa + hydrochlorothiazide): Arginine, Coenzyme Q10, Ephedra, Potassium, Vitamin B12
Alenic Alka (aluminum hydroxide + magnesium trisilicate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc
Alesse (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc
Alferon N (interferon alpha): Astragalus, Echinacea, Iron, Licorice, Zinc
Alimta (pemetrexed): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_{12}
Alka-Seltzer (aspirin + citric acid + sodium bicarbonate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin D, Zinc
Alkaban-AQ (vinblastine): Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin
Alkeran (melphalan): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Allegra (fexofenadine): St. John's Wort
Allercort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
alli (orlistat): Beta-Carotene, Coenzyme Q10, Vitamin A, Vitamin D, Vitamin E, Vitamin K
Allohexal (allopurinol): Carnitine, Copper, Iron, Tryptophan, Vitamin D
Aloprim (allopurinol): Carnitine, Copper, Iron, Tryptophan, Vitamin D
Alora Transdermal (estradiol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Alphaderm (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Alphatrex (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Altace (ramipril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc
Alternagel (aluminum hydroxide): Calcium, Cayenne, Chromium, Copper, Ephedra, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Zinc
Altocor (lovastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E
Altoprev (lovastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E
Alupent (metaproterenol): Calcium, Magnesium, Potassium
Alurate (aprobarbital): DHEA, Gotu Kola, Valerian, Vitamin B_2
Aluvia (lopinavir + ritonavir): Copper, Garlic, St. John's Wort, Vitamin C
Amaryl (glimepiride): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3
Ambien (zolpidem): 5-HTP, Gotu Kola, Melatonin, Valerian
AmBisome (amphotericin, liposomal): Echinacea
Amerge (naratriptan): 5-HTP, Feverfew, Tryptophan
Amficot (ampicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin C, Vitamin K, Zinc
Ami-Tex LA (guaifenesin + phenylpropanolamine): Potassium, Tyrosine
Amigesic (salsalate): Calcium, Folic Acid, Omega-3 Fatty Acids, Policosanol, Vitamin C, Vitamin K, Zinc
Amikin (amikacin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Amoxicot (amoxicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Amoxil (amoxicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Amphojel (aluminum hydroxide): Calcium, Cayenne, Chromium, Copper, Ephedra, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Zinc
Amytal (amobarbital): DHEA, Gotu Kola, Valerian, Vitamin B_2

Ana-Gard (epinephrine): Magnesium, Potassium, Vitamin C
Anacin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Anadrol-50 (oxymetholone): Echinacea
Anafranil (clomipramine): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Anandrone (nilutamide): Black Cohosh, Vitamin D
Anaprox (naproxen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Anaspaz (hyoscyamine): Iron
Anavar (oxandrolone): Echinacea
Ancef (cefazolin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Androcur (cyproterone): Black Cohosh, Vitamin D
Android (methyltestosterone): Beta-Carotene, DHEA, Vitamin A, Zinc
Andromaco Gliporal (buformin): Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}
Anectine (suxamethonium): Ginger, Magnesium
Anexsia (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Angiomax (bivalirudin): Cayenne, DHEA, Policosanol
Angiopine (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Angiopine LA (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Angiopine MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Anodynos-DHC (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Anquil (benperidol): Milk Thistle, Phenylalanine
Ansaid (furbiprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Zinc
Anspor (cephradine): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Antabus (disulfiram): Vitamin C
Antabuse (disulfiram): Vitamin C
Antagon (ganirelix): Black Cohosh
Anthra-Derm (anthralin): Vitamin E
Anturane (sulfinpyrazone): Vitamin B_2, Vitamin B_3
Apexicon (diflorasone): Aloe, Green Tea, Licorice, Vitamin C
Apo-Clonidine (clonidine): DHEA, Ephedra, Melatonin
Apo-Gemfibrozil (gemfibrozil): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc
Apo-Guanethidine (guanethidine): Ephedra, Vitamin B_3
Apo-Hydral (hydralazine): Melatonin, Vitamin B_6, Zinc
Apo-Hydralazine (hydralazine): Melatonin, Vitamin B_6, Zinc
Apo-Nifed (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Apo-Salvent (salbutamol): Potassium
Apo-Sulfasalazine (sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Apresazide (hydralazine + hydrochlorothiazide): Arginine, Coenzyme Q10, Melatonin, Potassium, Vitamin B_6
Apresoline (hydralazine): Melatonin, Vitamin B_6, Zinc
Apresoline Injection (hydralazine): Melatonin, Vitamin B_6, Zinc
Aprovel (irbesartan): Alpha-Lipoic Acid, Potassium
Aptivus (tipranavir): Copper, Garlic, St. John's Wort, Vitamin C
Aquazide (hydrochlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, ?>Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc
Aquest (estrone): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Aralen (chloroquine): Calcium, Magnesium, Vitamin B_2, Vitamin E
Aralen HCl (chloroquine): Calcium, Magnesium, Vitamin B_2, Vitamin E
Aranesp (darbepoetin alpha): Dang Gui, Iron, Vitamin B_6, Vitamin C
Aredia (pamidronate): Calcium, Iron, Magnesium, Vitamin D, Zinc
Arfonad (trimethaphan): Vitamin B_3
Argatroban (argatroban): Cayenne, DHEA, Policosanol
Aricept (donepezil): Ginkgo
Arimidex (anastrozole): Green Tea
Aristocort (triamcinolone, oral): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Arixtra (fondaparinux): Cayenne, Chondroitin Sulfate, DHEA, Policosanol
Arm-A-Med (isoetharine): Calcium, Magnesium, Potassium
Armour Thyroid (L-thyroxine + L-triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
Aromasin (exemestane): Green Tea
Aropax (paroxetine): 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc
Arthritis Foundation Pain Reliever (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Arthrotec (diclofenac + misoprostol): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Asacol (mesalazine): Vitamin B_{12}

Asasantin (acetylsalicylic acid + dipyridamole [extended-release]): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Ascriptin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Asendin (amoxapine): 5-HTP, Coenzyme Q10, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Aspergum (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Asprimox (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

AsthmaHaler (epinephrine): Magnesium, Potassium, Vitamin C

AsthmaNefrin (epinephrine): Magnesium, Potassium, Vitamin C

Astramorph PF (morphine): Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Atabrine (quinacrine): Vitamin B_2

Atacand (candesartan): Alpha-Lipoic Acid, Potassium

Atacand HCT (candesartan + hydrochlorothiazide): Alpha-Lipoic Acid, Potassium

Atamet (levodopa + carbidopa): 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Atapryl (selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

Ativan (lorazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Atragen (tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Atridox (doxycycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Atromid-S (clofibrate): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Iron, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Augmentin (amoxicillin + clavulanic acid): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Augmentin XR (amoxicillin + clavulanic acid): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Aurorix (moclobemide): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Avalide (irbesartan + hydrochlorothiazide): Alpha-Lipoic Acid, Potassium

Avandia (rosiglitazone): Chromium, Vitamin B_3

Avapro (irbesartan): Alpha-Lipoic Acid, Potassium

AVC (sulfanilamide): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Avelox (moxifloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Aventyl (nortriptyline): 5-HTP, Coenzyme Q10, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Avidart (dutasteride): Black Cohosh, Saw Palmetto

Avinza (morphine): Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Avita (tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Avlosulfon (dapsone): Folic Acid, Licorice, PABA, Probiotic Flora, Vitamin E, Vitamin K, Zinc

Avodart (dutasteride): Black Cohosh, Saw Palmetto

Avolve (dutasteride): Black Cohosh, Saw Palmetto

Axert (almotriptan): 5-HTP, Feverfew, Tryptophan

Axid (nizatidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc

Axid AR (nizatidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc

Aygestin (norethindrone, oral): Magnesium, St. John's Wort

Azactam injection (aztreonam): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin C, Vitamin K, Zinc

Azamun (azathioprine): Echinacea, Folic Acid, Vitamin B_3

Azilect (rasagiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine

Azopt ophthalmic suspension (brinzolamide, ophthalmic suspension): Potassium

Azulfidine (sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Azulfidine EN-Tabs (sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

B&O Supprettes (opium and belladonna): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Bactine (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Bactocill (oxacillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Bactrim (trimethoprim + sulfamethoxazole): Calcium, Folic Acid, Licorice, Magnesium, PABA, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin C, Vitamin K, Zinc

Bapadin (bepridil): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Basajel (aluminum carbonate gel): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Zinc

Baycol (cerivastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids,

Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Bayer Aspirin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Bayer Buffered Aspirin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Polico-sanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Bayer Low Adult Strength (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Beclovent (beclomethasone inhalant): Calcium

Beconase (beclomethasone inhalant): Calcium

Beconase AQ (beclomethasone inhalant): Calcium

Beepen-VK (penicillin V): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Bendectin (doxylamine + pyridoxine): Vitamin B_6

Benemid (probenecid): Vitamin B_2, Vitamin B_3, Vitamin C

Benicar (olmesartan): Alpha-Lipoic Acid, Potassium

Benperidol-neuraxpharm (benperidol): Milk Thistle, Phenylalanine

Benzamycin (erythromycin + benzoyl peroxide): Vitamin E, Zinc

Berotec (fenoterol): Calcium, Magnesium, Potassium

Beta-Adalat (atenolol + nifedipine): Arginine, Calcium, Coenzyme Q10, Dang Gui, Magnesium, Policosanol, Potassium, St. John's Wort, Vitamin C

Beta-HC (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Beta-Val (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Betachron (propranolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Policosanol, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Betaderm (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Betanate (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Betapace (sotalol): Calcium, Carnitine, Cascara, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Betapace AF (sotalol): Calcium, Carnitine, Cascara, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Betapen-VK (penicillin V): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Betatrex (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Bexophene (acetylsalicylic acid + propoxyphene): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Bextra (valdecoxib): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin C, Zinc

Bezalip (bezafibrate): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Biaxin (clarithromycin): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Bicillin C-R (penicillin G): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Bicillin L-A (penicillin G): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

BiDil (isosorbide dinitrate + hydralazine): Arginine, Carnitine, Folic Acid, Melatonin, Vitamin B_6, Vitamin C

Bifenabid (probucol): Beta-Carotene

Biltricide (praziquantl): Beta-Carotene, Vitamin A

Black-Draught (senna): Potassium

Blenoxane (bleomycin): Aloe, Echinacea, Eleuthero, Garlic, Ginseng, Licorice, Omega-3 Fatty Acids, Probiotic Flora, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin B_1, Vitamin C, Vitamin E, Vitamin K

Bleph-10 (sodium sulfacetamide): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Blocadren (timolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Bondronat (ibandronate): Calcium, Iron, Magnesium, Vitamin D, Zinc

Bonefos (clodronate): Calcium, Iron, Magnesium, Vitamin D, Zinc

Boniva (ibandronate): Calcium, Iron, Magnesium, Vitamin D, Zinc

Brelomax (tulobuterol): Calcium, Magnesium, Potassium

Brethaire (terbutaline): Potassium

Brethine (terbutaline): Potassium

Brevibloc (esmolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Brevicon (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Brevital (methohexital): DHEA, Gotu Kola, Valerian, Vitamin B_2

Bricanyl (terbutaline): Potassium

Bronchaid (epinephrine): Magnesium, Potassium, Vitamin C

Bronkaid Mist (epinephrine): Magnesium, Potassium, Vitamin C

Bronkometer (isoetharine): Calcium, Magnesium, Potassium

Bronkosol (isoetharine): Calcium, Magnesium, Potassium

Brontin Mist (epinephrine): Magnesium, Potassium, Vitamin C

Bufferin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Buffex (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo,

Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Buformina (buformin): Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Bumex (bumetanide): Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc

Buprenex (buprenorphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Buronil (melperon): Milk Thistle, Phenylalanine

Buspar (buspirone): 5-HTP, St. John's Wort, Tryptophan

Butisol (butabarbital): DHEA, Gotu Kola, Valerian, Vitamin B_2

Caci-IM (bacitracin): Licorice, Probiotic Flora, Vitamin K, Zinc

Caelyx (doxorubicin, pegylated liposomal): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin B_6, Vitamin E

Cafcit (caffeine): Calcium, Ephedra, Kava, Melatonin

Caffedrine (caffeine): Calcium, Ephedra, Kava, Melatonin

Calan (verapamil): Calcium, Carnitine, Folic Acid, Magnesium, Melatonin, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E

Calan SR (verapamil): Calcium, Carnitine, Folic Acid, Magnesium, Melatonin, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E

Calanif (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Calcimar (calcitonin): Calcium, Vitamin D

Calciparine (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Calcium Rich Rolaids (calcium carbonate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin D, Zinc

Caldecort Anti-Itch (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Cama Arthritis Pain Reliever (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Camcolit (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Camila (norethindrone, oral): Magnesium, St. John's Wort

Campto (irinotecan): Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

Camptosar (irinotecan): Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

Canasa (mesalazine): Vitamin B_{12}

Capital and Codeine (codeine + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Capoten (captopril): Arginine, Cayenne, Iron, Magnesium, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Capto-Co (captopril + hydrochlorothiazide): Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Captozide (captopril + hydrochlorothiazide): Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Carafate (sucralfate): Calcium, Vitamin D

Carbatrol (carbamazepine): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Carbex (selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

Carbolith (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Cardene (nicardipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Cardene I.V. (nicardipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Cardene SR (nicardipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Cardif (nitrendipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Cardilate MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Cardizem (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Cardizem CD (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Cardizem SR (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Cardura (doxazosin): Saw Palmetto, Vitamin B_2

Cartia XT (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John' Wort, Vitamin B_6, Vitamin D

Cartrol (carteolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Casodex (bicalutamide): Black Cohosh, Vitamin D

Cataflam (diclofenac): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Catapres Oral (clonidine): DHEA, Ephedra, Melatonin

Catapres-TTS Transdermal Dixarit (clonidine): DHEA, Ephedra, Melatonin

Ceclor (cefaclor): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cedax (ceftibuten): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefadyl (cephapirin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefizox (ceftizoxime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefobid (cefoperazone): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefotan (cefotetan): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Ceftin (cefuroxime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Cefzil (cefprozil): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Celebrex (celecoxib): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin C, Zinc
Celestone (betamethasone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Celexa (citalopram): 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B6, Vitamin B_{12}, Vitamin C, Zinc
CellCept (mycophenolate): Echinacea, Magnesium, Turmeric/Curcumin
Celontin (methsuximide): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Cenafed (pseudoephedrine): Potassium
Cenestin (conjugated synthetic estrogens): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Centrax (prazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3
Ceptaz (ceftazidime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Cerebyx (fosphenytoin): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Cerubidine (daunorubicin): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Ginseng, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E
Cetacort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Cetrotide (etrorelix): Black Cohosh
Chenix (chenodeoxycholic acid): *S*-Adenosylmethionine (SAMe), Vitamin B_2
Chimax (flutamide): Black Cohosh, Vitamin D
Chlor Trimeton (pseudoephedrine): Potassium
Chlorohex (chlorhexidine): Iron, Licorice, Probiotic Flora, Vitamin K, Zinc
Chloromycetin (chloramphenicol): Folic Acid, Iron, Licorice, Probiotic Flora, Vitamin B_{12}, Vitamin K, Zinc
Choledyl (oxtriphylline): Potassium
Choloxin (dextrothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
Chronulac (lactulose): Potassium
Cialis (tadalafil): Arginine
Cibacalcin (calcitonin): Calcium, Vitamin D
Ciloxan (ciprofloxacin): Calcium, Copper, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Cinobac (cinoxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Cipro (ciprofloxacin): Calcium, Copper, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Ciproterona (cyproterone): Black Cohosh, Vitamin D
Citrucel (methylcellulose): Potassium, Vitamin B_2
Claforan (cefotaxime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin C, Vitamin K, Zinc
Clavulin (amoxicillin + clavulanic acid): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Cleocin (clindamycin oral): Licorice, Probiotic Flora, Vitamin K, Zinc
Cleocin T (clindamycin topical): Zinc
Clexane (enoxaparin): Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C
Climagest (estradiol + norethindrone, oral): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Climara Transdermal (estradiol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Climens (estradiol valerate + cyproterone acetate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Climesse (estradiol + norethindrone, oral): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Clindaderm (clindamycin topical): Zinc
Clinoril (sulindac): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Cloderm (clocortolone): Aloe, Green Tea, Licorice, Vitamin C
Cloxapen (cloxacillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Clozaril (clozapine): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Selenium, Vitamin B_3, Vitamin B_6, Vitamin C
Co-Gesic (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Co-Magaldrox (aluminum hydroxide + magnesium hydroxide + simethicone): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc
Co-Proxamol (acetaminophen + dextropropoxyphene): Garlic, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C
Co-Tendione (atenolol + chlorthalidone): Arginine, Calcium, Coenzyme Q10, Policosanol, Potassium, Vitamin C
Co-Zidocapt (captopril + hydrochlorothiazide): Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Cogentin (benztropine): Vitamin B_3
Cognex (tacrine): Echinacea, Melatonin, Milk Thistle, Vitamin C
Colace (docusate): Magnesium, Potassium
Colestid (colestipol): Beta-Carotene, Calcium, Folic Acid, Iron, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

ColyMycin M (colistimethate): Licorice, Probiotic Flora, Vitamin K, Zinc
CoLyte (polyethylene glycol–electrolyte solution): Potassium
CombiPatch (estradiol + norethindrone patch): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Combipres (clonidine + chlorthalidone): Arginine, Coenzyme Q10, DHEA, Ephedra, Melatonin, Potassium
Combivent (albuterol + ipratropium bromide): Calcium, Magnesium, Potassium
Combivir (zidovudine + lamivudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc
Compazine (prochlorperazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Concerta (methylphenidate): 5-HTP, Iron, Reishi, Tyrosine, Zinc
Copegus (ribavirin): *S*-Adenosylmethionine (SAMe)
Coracten/SR/XL (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Cordarone (amiodarone): Cascara, Echinacea, Magnesium, Potassium, Vitamin B_6, Vitamin E
Cordran (flurandrenolide): Aloe, Green Tea, Licorice, Vitamin C
Corgard (nadolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B6, Vitamin C
Cormax (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc
Coroday MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Corsodyl (chlorhexidine): Iron, Licorice, Probiotic Flora, Vitamin K, Zinc
Cort-Dome (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Cortaid (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Cortef (hydrocortisone): Aloe, Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Green Tea, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Cortifair (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Cortizone (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Cortone (hydrocortisone): Aloe, Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Green Tea, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Cortril (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Corvert (ibutilide): Cascara, Magnesium, Potassium
Cosmegen (dactinomycin): Echinacea, Eleuthero, Ginseng, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K
Cosmegen Lyovac (dactinomycin): Echinacea, Eleuthero, Ginseng, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K
Cosopt (dorzolamide + timolol): Potassium
Cotrim (trimethoprim + sulfamethoxazole): Calcium, Folic Acid, Licorice, Magnesium, PABA, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin C, Vitamin K, Zinc
Coumadin (warfarin): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Echinacea, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Iron, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Zinc
Covera-HS (verapamil): Calcium, Carnitine, Folic Acid, Magnesium, Melatonin, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E
Cozaar (losartan): Alpha-Lipoic Acid, Potassium
Creg (carvedilol): Potassium
Crestor (rosuvastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E
Crixivan (indinavir): Copper, Garlic, St. John's Wort, Vitamin C
Cuprimine (penicillamine): Copper, Iron, Magnesium, Vitamin B_6, Zinc
Cutivate (fluticasone): Aloe, Green Tea, Licorice, Vitamin C
Cyclocort (amcinonide): Aloe, Green Tea, Licorice, Vitamin C
Cyclofem (estradiol cypionate + medroxyprogesterone acetate): Beta-Carotene, Folic Acid, Magnesium, Vitamin A, Vitamin B_3, Vitamin D
Cycrin (medroxyprogesterone, oral): Beta-Carotene, Calcium, Folic Acid, Magnesium, St. John's Wort, Vitamin A, Vitamin D
Cylert (pemoline): Reishi, Tyrosine
Cymbalta (duloxetine): 5-HTP, Folic Acid, Ginkgo, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}
Cyprohexal (cyproterone): Black Cohosh, Vitamin D
Cyprone (cyproterone): Black Cohosh, Vitamin D
Cyprostat (cyproterone acetate): Black Cohosh, Vitamin D, Vitex
Cyproteron (cyproterone): Black Cohosh, Vitamin D
Cyproteronum (cyproterone): Black Cohosh, Vitamin D
Cystodigin (digitoxin): Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort
Cystospaz (hyoscyamine): Iron
Cystospaz-M (hyoscyamine): Iron
Cytomel (L-triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
Cytosar-U (cytarabine): Echinacea, Eleuthero, Folic Acid, Ginseng, Vitamin B_1
Cytotec (misoprostol): Magnesium
Cytovene (ganciclovir): Astragalus
Cytoxan (cyclophosphamide): Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Carnitine, Echinacea, Eleuthero, Ginger, Ginseng, Licorice, Melatonin, Omega-3 Fatty Acids, Reishi, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E
Dalfon (fenoprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Dalmane (flurazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Daranide (dichlorphenamide): Potassium
Daraprim (pyrimethamine): Folic Acid, Iron
Darvocet-N (acetaminophen + propoxyphene): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Darvocet-N 100 (acetaminophen + propoxyphene): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Darvon (propoxyphene): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Darvon Compound (acetylsalicylic acid + caffeine + propoxyphene): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Darvon Compound-65 Pulvules (acetylsalicylic acid + propoxyphene): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Darvon-N (propoxyphene): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
DaunoXome (daunorubicin, liposomal): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Ginseng, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E
Daypro (oxaprozin): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
De-capeptyl Trelstar (triptorelin): Black Cohosh, Melatonin, Vitamin D
Debeone (phenformin): Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}
Deca-durabolin (nandrolone): Echinacea
Decaderm (dexamethasone): Aloe, Calcium, Ephedra, Green Tea, Licorice, Vitamin C
Decadron (dexamethasone): Aloe, Calcium, Ephedra, Green Tea, Licorice, Vitamin C
Decapryn (doxylamine): Vitamin B_6
Decaspray (dexamethasone): Aloe, Calcium, Ephedra, Green Tea, Licorice, Vitamin C
Declomycin (demeclocycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Decofed (pseudoephedrine): Potassium
Delacort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Delestrogen (estradiol valerate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Delta-Cortef (prednisolone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Deltasone (prednisone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Demadex (torsemide): Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc
Demerol (meperidine): Chromium, Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Demulen 1/35 (ethinyl estradiol + ethynodiol): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc
Demulen 1/50 (ethinyl estradiol + ethynodiol): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc
Dep-Gynogen (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Depacon (sodium valproate): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Depacon (valproate sodium): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Selenium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Depakene (valproic acid): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Selenium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Depakote Delayed Release (divalproex sodium): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Selenium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Depakote ER (divalproex sodium): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Selenium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Depen (penicillamine): Copper, Iron, Magnesium, Vitamin B_6, Zinc
Depo-Estradiol (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Depo-Provera (medroxyprogesterone, injection): Beta-Carotene, Calcium, Folic Acid, Vitamin A, Vitamin B_3, Vitamin D

Depo-subQ Provera 104 (medroxyprogesterone, injection): Beta-Carotene, Calcium, Folic Acid, Vitamin A, Vitamin B_3, Vitamin D

DepoCyt (cytarabine): Echinacea, Eleuthero, Folic Acid, Ginseng, Vitamin B_1

Depogen (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Deponit (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Deracyn (adinazolam): Kava, St. John's Wort

Derma-Smoothe/FS (fluocinolone): Aloe, Green Tea, Licorice, Vitamin C

Dermacort (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C

Dermarest (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C

DermiCort (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C

Dermotyl (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Dermoval (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Dermovate (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Dermovate-NN (neomycin + nystatin + clobetasol): Aloe, Beta-Carotene, Green Tea, Licorice, Vitamin C, Zinc

Dermoxin (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Dermtex HC (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Deroxat (paroxetine): 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Desferal (desferoxamine): Copper, Iron, Vitamin C

Desogen (ethinyl estradiol + desogestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

DesOwen (desonide): Aloe, Green Tea, Licorice, Vitamin C

Destolit (ursodeoxycholic acid): *S*-Adenosylmethionine (SAMe), Vitamin B_3

Desyrel (trazodone): 5-HTP, Ginkgo, St. John's Wort

Deteclo (chlortetracycline + demeclocycline + tetracycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Dex-A-Diet (phenylpropanolamine): Potassium, Tyrosine

Dexatrim (phenylpropanolamine): Potassium, Tyrosine

Dexedrine (dextroamphetamine): 5-HTP, Magnesium, Omega-3 Fatty Acids, Potassium, Reishi, Tyrosine, Vitamin B_6, Vitamin C, Zinc

Diabeta (glyburide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Diabinese (chlorpropamide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Diamox Sequels (acetazolamide): Coenzyme Q10, Ephedra, Potassium

Diamox (acetazolamide): Coenzyme Q10, Ephedra, Potassium

Dianabol (methandrostenolone): Echinacea, Milk Thistle

Dianben (metformin): Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Diastat (diazepam): Carnitine, DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Diclectin (doxylamine + pyridoxine): Vitamin B_6

Didronel (etidronate): Calcium, Iron, Magnesium, Vitamin D, Zinc

Diflucan (fluconazole): Echinacea, St. John's Wort

Digitek (digoxin): Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort, Vitamin D

Dilacor XR (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Dilantin (phenytoin): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Dilaudid-5 (hydromorphone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Dilaudid-HP (hydromorphone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Dilaudid (hydromorphone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Dilor (dyphylline): Potassium

Diltia XT (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Dimetapp Decongestant (pseudoephedrine): Potassium

Dindevan (phenindione): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Diovan (valsartan): Alpha-Lipoic Acid, Potassium

Diovan HCT (valsartan + hydrochlorothiazide): Alpha-Lipoic Acid, Potassium

Diprolene (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Diprolene AF (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Diprosone (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Disalcid (salsalate): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Policosanol, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin K, Zinc

Dithranol (anthralin): Vitamin E

Diucardin (hydroflumethiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Diuril (chlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc
Dobutrex (dobutamine): Calcium
Dolacet (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Dolobid (diflunisal): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Policosanol, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin K, Zinc
Dolophine (methadone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Donnamar (hyoscyamine): Iron
Doral (quazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3
Doryx (doxycycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Doxil (doxorubicin, pegylated liposomal): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin B_6, Vitamin E
Doxy (doxycycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Drenison (flurandrenolide): Aloe, Green Tea, Licorice, Vitamin C
DriCort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Dridol (droperidol): Milk Thistle, Phenylalanine
Drithocreme (anthralin): Vitamin E
Drixoral (pseudoephedrine): Potassium
Drogenil (flutamide): Black Cohosh, Vitamin D
DTIC-Dome (dacarbazine): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Duagen (dutasteride): Black Cohosh, Saw Palmetto
Dulcolax (bisacodyl tablets): Potassium
DuoCet (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Duofem (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort
Duphaston (dydrogesterone): Vitamin D, Vitex
Duprost (dutasteride): Black Cohosh, Saw Palmetto
Dura-Estrin (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Duraclon (clonidine): DHEA, Ephedra, Melatonin
Duragesic Transdermal (fentanyl): Ephedra, Ginger, Ginseng, Gotu Kola, Magnesium, Phenylalanine, Tyrosine
Duralith (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan
Duramorph (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Duricef (cefadroxil): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Dutagen (dutasteride): Black Cohosh, Saw Palmetto
Dutas (dutasteride): Black Cohosh, Saw Palmetto
Dyazide (triamterene + hydrochlorothiazide): Arginine, Calcium, Coenzyme Q10, Folic Acid, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Dycill (dicloxacillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Dymelor (acetohexamide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3
Dynabac (dirithromycin): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc
Dynacin (minocycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
DynaCirc (isradipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
DynaCirc CR (isradipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
DynaCirc I.V. (isradipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Dynapen (dicloxacillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Dyrenium (triamterene): Arginine, Calcium, Folic Acid, Glucosamine Sulfate, Magnesium, Potassium, Zinc
Easprin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Ecostatin (econazole): Echinacea
Ecotrin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Ecotrin Low Adult Strength (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
ED-SPAZ (hyoscyamine): Iron
Edecrin (ethacrynic acid): Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc
EES (erythromycin oral): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K, Zinc
Effexor (venlafaxine): 5-HTP, Folic Acid, Ginkgo, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}
Efidac (pseudoephedrine): Potassium
Efudex (fluorouracil): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginkgo, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E
Efudix (fluorouracil): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginkgo, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E
Elavil (amitriptyline): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Eldepryl (selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

Ellence (epirubicin): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Eloxatin (oxaliplatin): Alpha-Lipoic Acid, Astragalus, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Ginger, Ginkgo, Ginseng, Milk Thistle, Selenium, St. John's Wort, Vitamin E

Eltroxin (levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Eludril (chlorhexidine): Iron, Licorice, Probiotic Flora, Vitamin K, Zinc

Eminase (anistreplase): Astragalus

Empirin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Empirin with Codeine (acetylsalicylic acid + codeine): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K

Enbrel (etanercept): Echinacea

Endocet (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Endocodone (oxycodone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Endodan (acetylsalicylic acid + oxycodone): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Endoxana (cyclophosphamide): Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Carnitine, Echinacea, Eleuthero, Ginger, Ginseng, Licorice, Melatonin, Omega-3 Fatty Acids, Reishi, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

Enduron (methyclothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Enerjets (caffeine): Calcium, Ephedra, Kava, Melatonin

Entex LA (guaifenesin + phenylpropanolamine): Potassium, Tyrosine

Epifin (epinephrine): Magnesium, Potassium, Vitamin C

Epifoam (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Epinal (epinephrine): Magnesium, Potassium, Vitamin C

EpiPen (epinephrine): Magnesium, Potassium, Vitamin C

EpiPen Auto-Injector, injectable (epinephrine): Magnesium, Potassium, Vitamin C

Epitrate (epinephrine): Magnesium, Potassium, Vitamin C

Epivir (lamivudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Epogen (epoetin alpha): Dang Gui, Iron, Vitamin B_6, Vitamin C

Eposin (etoposide): Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort

Eppy/N (epinephrine): Magnesium, Potassium, Vitamin C

Eprex (epoetin alpha): Dang Gui, Iron, Vitamin B_6, Vitamin C

Equipoise (boldenone): Echinacea

Ergamisol (levamisole): Beta-Carotene, Echinacea, Vitamin A

Errin (norethindrone, oral): Magnesium, St. John's Wort

Ery-Tab (erythromycin oral): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K, Zinc

Erycette (erythromycin topical): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Eryderm (erythromycin topical): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Erygel (erythromycin topical): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

EryPed (erythromycin oral): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K, Zinc

Esbatal (betanidine): Ephedra

Escapelle (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Esidrix (hydrochlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Eskalith (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Essaven (topical) (heparin + phosphatidylcholine + Aescin): Horse Chestnut

Estinyl (ethinyl estradiol): Arginine, Boron, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Estra-D (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estra-L 40 (estradiol valerate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estrace (estradiol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estradot (estradiol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estragyn 5 (estrone): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estratab (esterified estrogens): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estratest (esterified estrogens + methyltestosterone): Beta-Carotene, Black Cohosh, Boron, Calcium, Copper, DHEA,

Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin A, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estratest H.S. (esterified estrogens + methyltestosterone): Beta-Carotene, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin A, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estreva (estradiol hemihydrate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estring (estradiol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estro-A (estrone): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estro-Cyp (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estroject-LA (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estrone '5' (estrone): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estronol-LA (estradiol cypionate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Estrostep (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ethide (ethionamide): Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Ethiocid (ethionamide): Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Ethomid (ethionamide): Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Ethrane (enflurane): Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Etomide (ethionamide): Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Etopophos (etoposide): Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort

Etrafon (amitriptyline + perphenazine): Coenzyme Q10, Echinacea, Milk Thistle, St. John's Wort, Vitamin B_{12}

Eulexin (flutamide): Black Cohosh, Vitamin D

Eumosone (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Eumovate (clobetasone): Aloe, Green Tea, Licorice, Vitamin C

Euthroid (L-thyroxine + L-triiodothyronine [synthetic]): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Euthyral (L-thyroxine + L-triiodothyronine [synthetic]): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Eutonyl (pargyline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_3

Evista (raloxifene): Black Cohosh, Dang Gui, Green Tea, Vitamin D

Excedrin IB (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_2, Vitamin B_6, Vitamin C, Zinc

Exirel (pirbuterol): Calcium, Magnesium, Potassium

Exjade (deferasirox): Vitamin C

Exna (benzthiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Extra Strength Adprin-B (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Extra Strength Bayer Enteric 500 Aspirin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Extra Strength Bayer Plus (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Ezide (hydrochlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Fabrazyme (agalsidase beta): Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Famvir (famciclovir): Astragalus

Fansidar (sulfadoxine + pyrimethamine): Folic Acid, Iron, Vitamin B_2

Fareston (toremifene): Black Cohosh, Dang Gui, Green Tea

Fasigyn (tinidazole): Milk Thistle

Faurin (fluvoxamine): 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Melatonin, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Felbatol (felbamate): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Feldene (piroxicam): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Femara (letrozole): Green Tea

FemHRT (estradiol + norethindrone, oral): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Femoston (estradiol + dydrogesterone): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Fenformin (phenformin): Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_1, Vitamin B_{12}

Fentanyl Oralet (fentanyl): Ephedra, Ginger, Ginseng, Gotu Kola, Magnesium, Phenylalanine, Tyrosine

FiberCon (polycarbophil): Potassium, Vitamin B_2

Fina (trenbolone): Echinacea

Fioricet (paracetamol + butalbital + caffeine): Calcium, DHEA, Ephedra, Garlic, Gotu Kola, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Valerian, Vitamin B_2, Vitamin C

Fiorinal (acetylsalicylic acid + codeine + butalbital + caffeine): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Flagyl (metronidazole, systemic): Licorice, Milk Thistle, Probiotic Flora, Vitamin K, Zinc

Fleet (Glycerin-containing Suppositories): Potassium

Fleet enema, Fleet Phospho-soda Oral Saline Laxative (monobasic sodium phosphate monohydrate + dibasic sodium phosphate heptahydrate): Potassium

Fletchers Castoria (senna): Potassium

Flexeril (cyclobenzaprine): Echinacea

Flomax (tamsulosin): Saw Palmetto, Vitamin B_3

Flomaxtra (tamsulosin): Saw Palmetto, Vitamin B_3

Florone (diflorasone): Aloe, Green Tea, Licorice, Vitamin C

Floxin (ofloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Fludara (fludarabine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Fluonex (fluocinonide): Aloe, Green Tea, Licorice, Vitamin C

Fluonid (fluocinolone): Aloe, Green Tea, Licorice, Vitamin C

Fluorigard (sodium fluoride): Calcium, Vitamin D

Fluorinse (sodium fluoride): Calcium, Vitamin D

Fluoritab (sodium fluoride): Calcium, Vitamin D

Fluorodex (sodium fluoride): Calcium, Vitamin D

Fluoroplex (fluorouracil): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginkgo, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Fluothane (halothane): Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Flura-Drops (sodium fluoride): Calcium, Vitamin D

Flura-Tab (sodium fluoride): Calcium, Vitamin D

Flurandrenolone (fludroxycortide): Aloe, Green Tea, Licorice, Vitamin C

Foamicon (magnesium trisilicate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc

Folex (methotrexate): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginseng, Iron, Melatonin, Milk Thistle, Omega-3 Fatty Acids, PABA, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E

Foradil (formoterol): Calcium, Magnesium, Potassium

Forane (isoflurane): Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Fortaz (ceftazidime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B1, Vitamin K, Zinc

Fortipine LA 40 (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Fortovase (saquinavir): Copper, Garlic, St. John's Wort, Vitamin C

Fosamax (alendronate): Calcium, Iron, Magnesium, Vitamin D, Zinc

Foscavir (foscarnet): Magnesium

Fragmin (dalteparin): Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Fraxiparine (nadroparin): Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Frenactil (benperidol): Milk Thistle, Phenylalanine

Frova (frovatriptan): 5-HTP, Feverfew, Tryptophan

FUDR (floxuridine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Fulvicin (griseofulvin): Echinacea, Vitamin B_3, Vitamin E

Fungisome (amphotericin, liposomal): Echinacea

Fungizone (amphotericin B): Calcium, Echinacea, Magnesium, Potassium

Furacin (nitrofurazone): Licorice, Probiotic Flora, Vitamin K, Zinc

Furadantin (nitrofurantoin): Licorice, Magnesium, Probiotic Flora, Vitamin B_6, Vitamin K, Zinc

Furoxone (furazolidone): Licorice, Probiotic Flora, Vitamin K, Zinc

G-mycin (gentamicin): Alpha-Lipoic Acid, Calcium, Carnitine, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitamin K

Gabitril (tiagabine): Carnitine, Folic Acid, Vitamin B_3

Gantanol (sulfamethoxazole): Calcium, Folic Acid, Licorice, Magnesium, PABA, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Gantrisin (sulfisoxazole): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Garamycin (gentamicin): Alpha-Lipoic Acid, Calcium, Carnitine, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitamin K

Gastrosed (hyoscyamine): Iron

Gaviscon Chewable (aluminum hydroxide + magnesium trisilicate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc

Gaviscon Regular Strength (magnesium trisilicate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc

Gemzar (gemcitabine): Aloe, Echinacea, Eleuthero, Folic Acid, Ginseng, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin B_1, Vitamin C, Vitamin E

Gen-Nifedipine (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Gen-Xene (clorazepate): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Tryptophan, Valerian,

Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Genaphed (pseudoephedrine): Potassium

GenCept 1/35 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Genora 1/35 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Genora 1/50 (mestranol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Gentlax (senna): Potassium

Geocillin (carbenicillin): Ginseng, Green Tea

Geodon (ziprasidone): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C

Glauctabs (methazolamide): Potassium

Gleevec (imatinib): St. John's Wort

Glianimon (benperidol): Milk Thistle, Phenylalanine

Glivec (imatinib): St. John's Wort

Glucobay (acarbose): Chromium, Vitamin B_3

Glucophage (metformin): Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Glucophage XR (metformin): Alpha-Lipoic Acid, Astragalus, Bilberry, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Glucotrol (glipizide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Glucotrol XL (glipizide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Glucovance (glyburide + metformin): Aloe, Alpha-Lipoic Acid, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Gly-Cort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Glynase (glyburide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Glynase Prestab (glyburide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

GoLYTELY (polyethylene glycol–electrolyte solution): Potassium

Grifulvin (griseofulvin): Echinacea, Vitamin B_3, Vitamin E

Gris-PEG (griseofulvin): Echinacea, Vitamin B_3, Vitamin E

Grisactin (griseofulvin): Echinacea, Vitamin B_3, Vitamin E

Gristatin (griseofulvin): Echinacea, Vitamin B_3, Vitamin E

Gynodiol (ethinyl estradiol): Arginine, Boron, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Gynogen L.A. 20 (estradiol valerate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Habitrol (nicotine transdermal patches): Vitamin B_3

Halcion (triazolam): DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3

Haldol (haloperidol): Alpha-Lipoic Acid, Chromium, Ginkgo, Iron, Kava, Melatonin, Milk Thistle, Phenylalanine, Potassium, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Halfprin 81 (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Halog (halcinonide): Aloe, Green Tea, Licorice, Vitamin C

Halotestin (fluoxymesterone): DHEA, Echinacea, Zinc

Harmonyl (reserpine): Ephedra, Reishi

Heartline (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Helidac (bismuth subsalicylate + metronidazole + tetracycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

HeliMet (lansoprazole + metronidazole + clarithromycin): Probiotic Flora

Hepalean (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Heparin Leo (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Herceptin (trastuzumab): Cascara, Green Tea

Hexalen (altretamine): Vitamin B_6

Hi-Cor (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C

Hivid (dideoxycytidine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Humanlog (insulin): Alpha-Lipoic Acid, Bilberry, Chromium, DHEA, Ephedra, Garlic, Ginkgo, Ginseng,

Glucosamine Sulfate, Horse Chestnut, Licorice, Magnesium, Milk Thistle, Omega-3 Fatty Acids, Potassium, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Humatin (paromomycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K

Humira (adalimumab): Echinacea

Humulin (insulin): Alpha-Lipoic Acid, Bilberry, Chromium, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Licorice, Magnesium, Milk Thistle, Omega-3 Fatty Acids, Potassium, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Hy-Phen (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Hycamtin (topotecan): Feverfew

Hydro-Tex (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C

Hydrocet (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Hydrocot (hydrochlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

HydroDiuril (hydrochlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Hydrogesic (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Hydromox (quinethazone): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Hygroton (chlorthalidone): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Hylorel (guanadrel): Ephedra

Hypnovel (midazolam): DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3

Hypolar Retard 20 (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Hytone (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C

Hytrin (terazosin): Saw Palmetto, Vitamin B_3

Hyzaar (losartan + hydrochlorothiazide): Alpha-Lipoic Acid, Arginine, Calcium, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Idamycin (idarubicin): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Ifex (ifosfamide): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Iletin (insulin): Alpha-Lipoic Acid, Bilberry, Chromium, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Licorice, Magnesium, Milk Thistle, Omega-3 Fatty Acids, Potassium, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Imdur (isosorbide mononitrate): Arginine, Carnitine, Folic Acid, Vitamin C

Imitrex (sumatriptan): 5-HTP, Feverfew, Tryptophan

Imodium A-D (loperamide): St. John's Wort

Imodium A-D Caplets (loperamide): St. John's Wort

Imuran (azathioprine): Echinacea, Folic Acid, Vitamin B_3

Inapsine (droperidol): Milk Thistle, Phenylalanine

Inderal (propranolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Policosanol, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B6, Vitamin C, Vitamin E

Inderal LA (propranolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Policosanol, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Inderex (propranolol + bendrofluazide): Arginine, Calcium, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Policosanol, Potassium, Vitamin C, Vitamin D, Zinc

Indocin (indomethacin): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin A, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Indocin-SR (indomethacin): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin A, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Infumorph (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

INH (isoniazid): Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E

Inhibace (cilazapril): Alpha-Lipoic Acid, Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Innohep (tinzaparin): Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Innopran XL (propranolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Policosanol, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Integrelin (eptifibatide): Cayenne, Ginger, Policosanol, *S*-Adenosylmethionine (SAMe)

Intron A (interferon alpha): Astragalus, Echinacea, Iron, Licorice, Zinc

Inversine (mecamylamine): Vitamin B_3

Invirase (saquinavir): Copper, Garlic, St. John's Wort, Vitamin C

Ipocal (mesalazine): Vitamin B_{12}

Iprivask (desirudin): Cayenne, DHEA, Policosanol

ISDN (isosorbide dinitrate): Arginine, Carnitine, Folic Acid, Vitamin C

Ismelin (guanethidine): Ephedra, Vitamin B_3

ISMN (isosorbide mononitrate): Arginine, Carnitine, Folic Acid, Vitamin C

ISMO (isosorbide mononitrate): Arginine, Carnitine, Folic Acid, Vitamin C

Isoptin/SR/XL (verapamil): Calcium, Carnitine, Folic Acid, Magnesium, Melatonin, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E

Isopto Hyoscine Ophthalmic (scopolamine): Dang Gui, Vitamin B_1

Isordil (isosorbide dinitrate): Arginine, Carnitine, Folic Acid, Vitamin C

Isotrate (isosorbide mononitrate): Arginine, Carnitine, Folic Acid, Vitamin C

Isuprel (isoproterenol): Garlic

Jadelle (levonorgestrel, implant): Magnesium, St. John's Wort

Janimine (imipramine): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Jarsin (phenprocoumon): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Jenamicin (gentamicin): Alpha-Lipoic Acid, Calcium, Carnitine, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitamin K

Jenest-28 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Jolivette (norethindrone, oral): Magnesium, St. John's Wort

Jumex (selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

Kadian (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Kaletra (lopinavir + ritonavir): Copper, Garlic, St. John's Wort, Vitamin C

Kantrex (kanamycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K

Kaopectate 1-D (loperamide): St. John's Wort

Karidium (sodium fluoride): Calcium, Vitamin D

Karvea (irbesartan): Alpha-Lipoic Acid, Potassium

Keflex (cephalexin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Keftab (cephalexin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Kefurox (cefuroxime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Kefzol (cefazolin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Kemstro (baclofen): Phenylalanine

Keppra (levetiracetam): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Kerlone (betaxolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Kestrone-5 (estrone): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Klonopin (clonazepam): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Kondremul Plain (mineral oil): Beta-Carotene, Calcium, Potassium, Vitamin A, Vitamin D, Vitamin E, Vitamin K

Konsyl-D (psyllium): Potassium, Vitamin B_2

Kwell Shampoo (lindane): Vitamin E

LactiCare-HC (hydrocortisone 17-butyrate/acetate/propbutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Lanacort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Laniazid (isoniazid): Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E

Lanoxicaps (digoxin): Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort, Vitamin D

Lanoxin (digoxin): Calcium, Cascara, Dang Gui, Eleuthero, Ephedra, Hawthorn, Licorice, Magnesium, Potassium, St. John's Wort, Vitamin D

Lanvis (thioguanine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_3

Largactil (chlorpromazine): Chromium, Coenzyme Q10, Ginkgo, Kava, Melatonin, Milk Thistle, Reishi, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E

Largon (propiomazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Lasix (furosemide): Calcium, Folic Acid, Ginseng, Glucosamine Sulfate, Licorice, Magnesium, Potassium, Vitamin B_1, Vitamin B_6, Vitamin C, Zinc

Ledercillin VK (penicillin V): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Lemoderm (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Lendormin (brotizolam): Kava, St. John's Wort

Lescol (fluvastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Lescol XL (fluvastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Lesterol (probucol): Beta-Carotene

Leukeran (chlorambucil): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Leukine (GMCSF): Echinacea

Leustatin (cladribine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Levaquin (levofloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Levatol (penbutolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Levbid (hyoscyamine): Iron

Levitra (vardenafil): Arginine

Levlen (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Levlite (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's

Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Levo-Dromoran (levorphanol): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Levo-T (levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Levonelle (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Levonelle-2 (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Levora 0.15/30 (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Levothroid (levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Levoxyl (levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Levsin (hyoscyamine): Iron

Levsin/SL (hyoscyamine): Iron

Levsinex (hyoscyamine): Iron

Lexapro (escitalopram): Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Lexiva (fosamprenavir): Copper, Garlic, St. John's Wort, Vitamin C

Lexotan (bromazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Lexxel (enalapril + felodipine): Arginine, Calcium, Cayenne, Coenzyme Q10, Iron, Potassium, St. John's Wort, Zinc

Li-Liquid (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Libritabs (chlordiazepoxide): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Librium (chlordiazepoxide): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Lidex-E (fluocinonide): Aloe, Green Tea, Licorice, Vitamin C

Lidex (fluocinonide): Aloe, Green Tea, Licorice, Vitamin C

Lincocin (lincomycin): Licorice, Probiotic Flora, Vitamin K, Zinc

Lioresal (baclofen): Phenylalanine

Lipitor (atorvastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Liquid Pred (prednisone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Liskonum (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Litarex (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Lithane (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Lithobid (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Lithonate (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Lithotabs (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

Lo/Ovral (ethinyl estradiol + norgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Lobate (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Locholest (cholestyramine): Beta-Carotene, Calcium, Folic Acid, Iron, Magnesium, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

Locoid (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Lodine (etodolac): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Lodosyn (carbidopa): 5-HTP, Folic Acid, Iron, Kava, *S*-Adenosylmethionine (SAMe), Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Loestrin (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Lofibra (fenofibrate): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Zinc

Lonide (fluocinonide): Aloe, Green Tea, Licorice, Vitamin C

Lopid (gemfibrozil): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Lopressor (metoprolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Lopressor HCT (metoprolol + hydrochlorothiazide): Arginine, Calcium, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Policosanol, Potassium, Vitamin C, Vitamin D, Zinc

Lopurin (allopurinol): Carnitine, Copper, Iron, Tryptophan, Vitamin D

Lorabid (loracarbef): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_3, Vitamin K, Zinc

Lorcet 10/650 (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Lorcet Plus (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Lorcet-HD (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Lorelco (probucol): Beta-Carotene

Lortab (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Lortab ASA (hydrocodone + acetylsalicylic acid): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Losec (omeprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Vitamin E, Zinc

Lotensin (benazepril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Lotrel (amlodipine + benazepril): Arginine, Calcium, Cayenne, Coenzyme Q10, DHEA, Potassium, St. John's Wort

Lovenox (enoxaparin): Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Lozol (indapamide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Lufyllin (dyphylline): Potassium

Luminol (phenobarbital): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Reishi, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Lunelle (estradiol cypionate + medroxyprogesterone acetate): Beta-Carotene, Folic Acid, Magnesium, Vitamin A, Vitamin B_3, Vitamin D

Lunesta (eszopiclone): 5-HTP, Gotu Kola, Melatonin, Valerian

Lupron (leuprolide): Black Cohosh, Vitamin D

Luride (sodium fluoride): Calcium, Vitamin D

Lurselle (probucol): Beta-Carotene

Luvox (fluvoxamine): 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Melatonin, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Luxiq (betamethasone): Aloe, Green Tea, Licorice, Vitamin C

Lynoral (ethinyl estradiol): Arginine, Boron, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Lyrica (pregabalin): Vitamin B_3

Maalox (aluminum hydroxide + magnesium hydroxide + simethicone): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc

Maalox Anti-Diarrheal (loperamide): St. John's Wort

Macrobid (nitrofurantoin): Licorice, Magnesium, Probiotic Flora, Vitamin B_6, Vitamin K, Zinc

Macrodantin (nitrofurantoin): Licorice, Magnesium, Probiotic Flora, Vitamin B_6, Vitamin K, Zinc

Madopar (levodopa + benserazide): 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Majeptil (thioproperazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_5, Vitamin C

Malarone (atovaquone + proguanil): Vitamin B_2

Mandol (cefamandole): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Manerix (moclobemide): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Marcumar (phenprocoumon): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Marevan (warfarin): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Echinacea, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Iron, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Zinc

Margesic H (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Marplan (isocarboxazid): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Marthritic (salsalate): Calcium, Folic Acid, Omega-3 Fatty Acids, Policosanol, Vitamin C, Vitamin K, Zinc

Matulane (procarbazine): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Mavik (trandolapril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Maxalt (rizatriptan): 5-HTP, Feverfew, Tryptophan

Maxaquin (lomefloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Maxiflor (diflorasone): Aloe, Green Tea, Licorice, Vitamin C

Maxipime (cefepime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Maxivate (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Maxtrex (methotrexate): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginseng, Iron, Melatonin, Milk Thistle, Omega-3 Fatty Acids, PABA, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E

Maxzide (triamterene + hydrochlorothiazide): Arginine, Calcium, Coenzyme Q10, Folic Acid, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Mebaral (mephobarbital): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Meclomen (meclofenamate): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Medihaler-Epi (epinephrine): Magnesium, Potassium, Vitamin C

Medihaler-Iso (isoproterenol): Garlic

Medipain 5 (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Medrol (methylprednisolone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Mefoxin (cefoxitin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Mellaril (thioridazine): Coenzyme Q10, Milk Thistle, Potassium, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin D

Melphalan (phenylalanine mustard): Astragalus, Carnitine, Echinacea, Eleuthero, Ginger, Selenium

Menest (esterified estrogens): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Mepacrine (quinacrine): Vitamin B_2

Meridia (sibutramine): 5-HTP, Tryptophan

Merrem I.V. (meropenem): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Mesantoin (fosphentoin): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Mesigyna (norethisterone enanthate + estradiol valerate): Magnesium, Vitamin B_3

Metadate (methylphenidate): 5-HTP, Iron, Reishi, Tyrosine, Zinc

Metaglip (glipizide + metformin): Aloe, Alpha-Lipoic Acid, Calcium, Chromium, Coenzyme Q10, DHEA, Ephedra, Folic Acid, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin B_{12}

Metamucil (psyllium): Potassium, Vitamin B_2

Methadose (methadone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Methitest (methyltestosterone): Beta-Carotene, DHEA, Vitamin A, Zinc

Methylin (methylphenidate): 5-HTP, Iron, Reishi, Tyrosine, Zinc

Meticorten (prednisone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

MetroGel Vaginal (metronidazole, vaginal): Zinc

Mevacor (lovastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Mexitil (mexiletine): Cascara, Magnesium, Potassium, Vitamin C

Mezlin (mezlocillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Miacalcin Nasal (calcitonin): Calcium, Vitamin D

Micanol Cream (anthralin): Vitamin E

Micardis (telmisartan): Alpha-Lipoic Acid, Potassium

Microlut (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Micronase (glyburide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Micronor (norethindrone, oral): Magnesium, St. John's Wort, Vitamin D

Microval (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Microzide (hydrochlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Midamor (amiloride): Arginine, Calcium, Folic Acid, Glucosamine Sulfate, Magnesium, Potassium, Zinc

Milkinol (mineral oil): Beta-Carotene, Calcium, Potassium, Vitamin A, Vitamin D, Vitamin E, Vitamin K

Milontin (phensuximide): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Minihep (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Minihep Calcium (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Minipress (prazosin): Saw Palmetto, Vitamin B_3

Minitran (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Minocin (minocycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Miradon (anisindione): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Miralax (polyethylene glycol): Potassium

Mirena (intrauterine L-norgestrel system): Vitamin D

Mithracin (plicamycin): Ginseng

Mitoxana (ifosfamide): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Mivacron (mivacurium): Magnesium

Mobic (meloxicam): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Modalim (ciprofibrate): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Modecate (fluphenazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Modicon (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Modrasone (alclometasone): Aloe, Green Tea, Licorice, Vitamin C

Moduretic (amiloride + hydrochlorothiazide): Arginine, Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Mono Gesic (salsalate): Calcium, Folic Acid, Omega-3 Fatty Acids, Policosanol, Vitamin C, Vitamin K, Zinc

Mono-Embolex (certoparin): Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Monodox (doxycycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Monoket (isosorbide mononitrate): Arginine, Carnitine, Folic Acid, Vitamin C

Monoparin (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Monoparin Calcium (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Monopril (fosinopril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Motrin (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Motrin IB (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Movergan (selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

Moxilin (amoxicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

MS Contin (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

MSIR (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Multiparin (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Mustargen (mechlorethamine): Astragalus, Carnitine, Echinacea, Eleuthero, Ginger, Selenium, Turmeric/Curcumin

Mutamycin (mitomycin): Echinacea, Eleuthero, Ginseng, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K

Myambutol (ethambutol): Copper, Folic Acid, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Zinc

Mycelex (clotrimazole): Probiotic Flora, Vitamin B_2

Mycifradin (neomycin): Alpha-Lipoic Acid, Beta-Carotene, Calcium, Eleuthero, Folic Acid, Ginger, Ginkgo, Horse Chestnut, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin D, Vitamin K

Myciguent (neomycin): Alpha-Lipoic Acid, Beta-Carotene, Calcium, Eleuthero, Folic Acid, Ginger, Ginkgo, Horse Chestnut, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin D, Vitamin K

Mycolog II (triamcinolone + nystatin): Licorice

MyCort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Mycostatin (nystatin): Echinacea, Zinc

Mycostatin (topical) (nystatin, topical): Echinacea

Mycotuf (ethionamide): Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Mykrox (metolazone): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Mylanta (aluminum hydroxide + magnesium hydroxide + simethicone): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc

Myleran (busulfan): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Myobid (ethionamide): Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Myocet (doxorubicin, pegylated liposomal): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin B_6, Vitamin E

Mysoline (primidone): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Naprosyn (naproxen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Naqua (trichlormethiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Narcan (naloxone): Phenylalanine

Nardil (phenelzine): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6

Naturetin (bendroflumethiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Navelbine (vinorelbine): Echinacea, Eleuthero, St. John's Wort

Navidrex (cyclopenthiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Nebcin (tobramycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K

Nebilet (nebivolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

NebuPent (pentamidine): Magnesium

Necon 0.5/30 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Necon 1/25 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Necon 1/50 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Necon 10/11 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle,

S-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Neggram (nalidixic acid): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Nelova 1/35 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Nelova 1/50 (mestranol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Nelova 10/11 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Nelulen 1/25 (ethinyl estradiol + ethynodiol): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Nelulen 1/50 (ethinyl estradiol + ethynodiol): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Nembutal (pentobarbital): Calcium, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Neo-Cultol (mineral oil): Beta-Carotene, Calcium, Potassium, Vitamin A, Vitamin D, Vitamin E, Vitamin K

Neo-Estrone (esterified estrogens): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Neo-Fradin (neomycin): Alpha-Lipoic Acid, Beta-Carotene, Calcium, Eleuthero, Folic Acid, Ginger, Ginkgo, Horse Chestnut, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin B_{12}, Vitamin D, Vitamin K

Neoproxil (cyproterone): Black Cohosh, Vitamin D

Neoral (cyclosporine): Arginine, Echinacea, Ginkgo, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, St. John's Wort, Turmeric/Curcumin, Vitamin C, Vitamin E, Zinc

NeoRecormon (epoetin beta): Dang Gui, Iron, Vitamin B_6, Vitamin C

Neosar (cyclophosphamide): Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Carnitine, Echinacea, Eleuthero, Ginger, Ginseng, Licorice, Melatonin, Omega-3 Fatty Acids, Reishi, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

NeoTab (neomycin): Alpha-Lipoic Acid, Beta-Carotene, Calcium, Eleuthero, Folic Acid, Ginger, Ginkgo, Horse Chestnut, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin D, Vitamin K

Neptazane (methazolamide): Potassium

Nerisona (diflucortolone): Aloe, Green Tea, Licorice, Vitamin C

Nerisone (diflucortolone): Aloe, Green Tea, Licorice, Vitamin C

Netromycin (netilmicin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K

Neulasts: Echinacea

Neuleptil (pericyazine): Coenzyme Q10, Milk Thistle, Vitamin B_3, Vitamin B_3, Vitamin C

Neumega: Echinacea

Neupogen: Echinacea

Neurontin (gabapentin): Carnitine, Folic Acid, Vitamin B_3, Vitamin B_6, Vitamin D

Nexium (esomeprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc

Niaspan (simvastatin + extended-release nicotinic acid): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

NicoDerm CQ (nicotine transdermal patches): Vitamin B_3

Nicotrol (nicotine transdermal patches): Vitamin B_3

Nifedipress MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nifedotard 20 MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nifelease (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nifopress Retard (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nighttime Sleep Aid (doxylamine): Vitamin B_6

Nilandron (nilutamide): Black Cohosh, Vitamin D

Nilstat (nystatin): Echinacea, Zinc

Nilstat (topical) (nystatin, topical): Echinacea

Nimbex (cisatracurium): Magnesium

Nimodrel MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nimotop (nimodipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Nipent (pentostatin): Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Nitrek (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitrepin (nitrendipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Nitro-Bid (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitro-Dur (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitro-Time (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitrodisc (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitrogard (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitroglyn (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitrol (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitrolingual (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nitrostat (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Nivaten Retard (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nivemycin (neomycin): Alpha-Lipoic Acid, Beta-Carotene, Calcium, Eleuthero, Folic Acid, Ginger, Ginkgo, Horse Chestnut, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin A, Vitamin B_1, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin D, Vitamin K

Nizoral (ketoconazole): Black Cohosh, Echinacea, Green Tea, Vitamin D

Nobrium (medazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

NoDoz (caffeine): Calcium, Ephedra, Kava, Melatonin

Nolvadex (tamoxifen): Black Cohosh, Calcium, Dang Gui, Feverfew, Ginseng, Green Tea, Melatonin, Omega-3 Fatty Acids, Vitamin A, Vitamin C, Vitamin E

Nootropyl (piracetam): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Nor-QD (norethindrone, oral): Magnesium, St. John's Wort

Norco (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Norcuron (vecuronium): Ginger, Magnesium

Nordette (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Norethin 1/50 (mestranol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Norgeston (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Norinyl 1/35 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Noristerat (norethindrone, injectable): Magnesium, St. John's Wort, Vitamin B_3

Norlestin 1/50 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

NorLevo (levonorgestrel, oral post-coital contraceptive): Magnesium, St. John's Wort

Normiflo (ardeparin): Cayenne, Chondroitin Sulfate, DHEA, Policosanol, Vitamin C

Normodyne (labetalol): Potassium

Noroxin (norfloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Norpace (disopyramide): Cascara, Magnesium, Potassium

Norplant-2 (levonorgestrel, implant): Magnesium, St. John's Wort

Norplant (levonorgestrel, implant): Magnesium, St. John's Wort

Norpramin (desipramine): 5-HTP, Coenzyme Q10, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Norvasc (amlodipine): Calcium, Carnitine, DHEA, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Norvir (ritonavir): Copper, Garlic, St. John's Wort, Vitamin C

Novantrone (mitoxantrone): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Novo-Clonidine (clonidine): DHEA, Ephedra, Melatonin

Novo-Gemfibrozil (gemfibrozil): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Novo-Hylazin (hydralazine): Melatonin, Vitamin B_6, Zinc

Novo-Nifedin (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Novolin (insulin): Alpha-Lipoic Acid, Bilberry, Chromium, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Licorice, Magnesium, Milk Thistle, Omega-3 Fatty Acids, Potassium, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

NovoRapid (insulin): Alpha-Lipoic Acid, Bilberry, Chromium, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Licorice, Magnesium, Milk Thistle, Omega-3 Fatty Acids, Potassium, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Noxafil (posaconazole): Echinacea, St. John's Wort

Nozinan (methotrimeprazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Nu-Clonidine (clonidine): DHEA, Ephedra, Melatonin

Nu-Nifed (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nu-Nifedipine-PA (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Nuclav (amoxicillin + clavulanic acid): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

NuLytely (polyethylene glycol-electrolyte solution): Potassium

Numorphan (oxymorphone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Nuprin (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Nutracort (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C

Nuvaring (etonogestrel/ethinyl estradiol vaginal ring): Arginine, Copper, Dang Gui, Iron, Licorice, Magnesium, Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Zinc

Nydrazid (isoniazid): Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E

Nyquil (acetaminophen + chlorpheniramine + dextromethorphan + pseudoephedrine + alcohol): Garlic, Licorice,

Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C

Nystex (nystatin): Echinacea, Zinc

Nystex Ointment (nystatin, topical): Echinacea

Nystop (nystatin, topical): Echinacea

Ocuflox (ofloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Ogen (estropipate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Olean (olestra): Vitamin K

Olux (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Omnicef (cefdinir): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Omnipen (ampicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin C, Vitamin K, Zinc

Oncovin (vincristine): Alpha-Lipoic Acid, Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin

Onkotrone (mitoxantrone): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Oralin (insulin): Alpha-Lipoic Acid, Bilberry, Chromium, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Horse Chestnut, Licorice, Magnesium, Milk Thistle, Omega-3 Fatty Acids, Potassium, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Oramorph SR (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Orapred (prednisolone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Orasone (prednisone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Oretic (hydrochlorothiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Orgaran (danaparoid): Cayenne, Chondroitin Sulfate, DHEA, Policosanol

Orinase (tolbutamide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3

Oro-Clense (chlorhexidine): Iron, Licorice, Probiotic Flora, Vitamin K, Zinc

Ortho Dienestrol (dienestrol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Ortho Novum 1/35 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ortho Novum 10/11 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ortho Novum 7/7/7 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ortho-Est (estropipate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Ortho-Micronor (norethindrone, oral): Magnesium, St. John's Wort

Ortho-Novum 1/50 (mestranol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ortho-Prefest (estradiol + norgestimate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Ortho-TriCyclen (ethinyl estradiol + desogestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Orudis (ketoprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Oruvail (ketoprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Ostac (clodronate): Calcium, Iron, Magnesium, Vitamin D, Zinc

Ovcon-35 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ovcon-50 (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ovral (ethinyl estradiol + norgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Ovrette (norgestrel, oral): Magnesium, St. John's Wort
OxyContin (oxycodone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
OxyIR (oxycodone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Pamelor (nortriptyline): 5-HTP, Coenzyme Q10, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Pandel (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Panesclerina (probucol): Beta-Carotene
Papaveretum (morphine hydrochloride + codeine hydrochloride + papaverine hydrochloride): Ephedra, Ginger, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Paraflex (chlorzoxazone): Garlic, St. John's Wort
Parafon Forte (chlorzoxazone): Garlic, St. John's Wort
Paraplatin (carboplatin): Alpha-Lipoic Acid, Astragalus, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Ginger, Ginkgo, Ginseng, Milk Thistle, Selenium, Turmeric/Curcumin
Parbenem (probenecid): Vitamin B_2, Vitamin B_3, Vitamin C
Parcopa (levodopa + carbidopa): 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_2, Vitamin B_6, Vitamin C, Vitex
Pariet (rabeprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc
Parnate (tranylcypromine): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Ginkgo, Ginseng, Licorice, Melatonin, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_6
Paser (para-aminosalicylic acid): Vitamin B_{12}
Pavulon (pancuronium): Magnesium
Paxene (paclitaxel): Aloe, Beta-Carotene, Echinacea, Eleuthero, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, PABA, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E
Paxil (paroxetine): 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc
PC-Cap (acetylsalicylic acid + propoxyphene): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
PCE Dispertab (erythromycin oral): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K, Zinc
Pedi Dri Topical Powder (nystatin, topical): Echinacea
PediaCare Fever Drops (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
PediaCare Infant Drops (pseudoephedrine): Potassium
Pediaflor (sodium fluoride): Calcium, Vitamin D
Pediapred (prednisolone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc
Pediazole (erythromycin oral): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K, Zinc
Peg-Intron: Enchinacea
Peganone (ethotoin): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Pen-Vee K (penicillin V): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Penecort (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Penetrex (enoxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Pentacarinat (pentamidine): Magnesium
Pentacort (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Pentam 300 (pentamidine): Magnesium
Pentasa (mesalazine): Vitamin B_{12}
Pentothal (thiopental): DHEA, Gotu Kola, Valerian, Vitamin B_2
Pentoxil (pentoxifylline): Arginine, Cayenne, Coenzyme Q10, Policosanol, Vitamin E
Pepcid RPD (famotidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc
Pepcid (famotidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc
Pepcid AC (famotidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc
Pepto Diarrhea Control (loperamide): St. John's Wort
Percocet 10/650 (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Percocet 2.5/325 (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Percocet 5/325 (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Percocet 7.5/500 (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Percodan (acetylsalicylic acid + oxycodone): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Percodan-Demi (acetylsalicylic acid + oxycodone): Calcium, Cayenne, Devil's Claw, Ephedra, Feverfew, Folic Acid, Ginkgo, Ginseng, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Phenylalanine, Policosanol, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Percolone (oxycodone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Peridex (chlorhexidine): Iron, Licorice, Probiotic Flora, Vitamin K, Zinc
Periochip (chlorhexidine): Iron, Licorice, Probiotic Flora, Vitamin K, Zinc
Periogard Oral Rinse (chlorhexidine): Iron, Licorice, Probiotic Flora, Vitamin K, Zinc

Periostat (doxycycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Permitil (fluphenazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Permole (dipyridamole): Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Iron, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)

Persantine (dipyridamole): Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Iron, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)

Pertofrane (desipramine): 5-HTP, Coenzyme Q10, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin E, Zinc

Petrogalar Plain (mineral oil): Beta-Carotene, Calcium, Potassium, Vitamin A, Vitamin D, Vitamin E, Vitamin K

Pfizerpen (penicillin G): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Pharmorubicin (epirubicin): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Phenaphen with Codeine (codeine + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Phenergan (promethazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Phenidone (1-Phenyl-3-Pyrazolidone): Vitamin A

Phenldrine (phenylpropanolamine): Potassium, Tyrosine

Phenoxine (phenylpropanolamine): Potassium, Tyrosine

Phenytek (phenytoin): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Phillips Milk of Magnesia Magnesium Citrate Solution (magnesium-containing products): Potassium

Phillips' Milk of Magnesia MOM (magnesium hydroxide): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin D, Vitex, Zinc

PhosLo (calcium acetate): Calcium

Phyllocontin (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6

Pipracil (piperacillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Pitocin (oxytocin): Ephedra

Plan B (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Plaquenil (hydroxychloroquine): Calcium, Magnesium, Vitamin B_2, Vitamin B_6, Vitamin D

Platinol-AQ (cisplatin): Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Calcium, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Feverfew, Ginger, Ginkgo, Ginseng, Magnesium, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Potassium, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin B_6, Vitamin C, Vitamin E, Zinc

Platinol (cisplatin): Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Calcium, Carnitine, Cayenne, Chondroitin Sulfate, Echinacea, Eleuthero, Feverfew, Ginger, Ginkgo, Ginseng, Magnesium, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Potassium, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin B_6, Vitamin C, Vitamin E, Zinc

Plavix (clopidogrel): Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)

Plendil (felodipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Pletal (cilostazol): Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)

PMS-Lithium (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan

PMS-Nifedipine (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

PMS-Sulfasalazine (sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Pneumopent (pentamidine): Magnesium

Pondocillin (pivampicillin): Carnitine

Ponstel (mefenamic acid): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B3, Vitamin B6, Vitamin C, Zinc

Postinor-2 (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Prandin (repaglinide): Chromium, Vitamin B_3

Pravachol (pravastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E

Precose (acarbose): Chromium, Vitamin B3

Prelone (prednisolone): Calcium, Cayenne, Chromium, DHEA, Echinacea, Ephedra, Folic Acid, Horse Chestnut, Licorice, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, Selenium, Vitamin A, Vitamin B_6, Vitamin C, Vitamin D, Vitamin K, Zinc

Premarin (conjugated equine estrogens): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Premelle cycle 5 (medroxyprogesterone + conjugated equine estrogens): Arginine, Beta-Carotene, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin A, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Prempak-C (conjugated equine estrogens + norgestrel): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Prempro (medroxyprogesterone + conjugated equine estrogens): Arginine, Beta-Carotene, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin A, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Pres Tab (glyburide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3, Vitamin E

Prevacid (lansoprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, Probiotic Flora, St. John's Wort, Vitamin B_{12}, Zinc

Prevalite (cholestyramine): Beta-Carotene, Calcium, Folic Acid, Iron, Magnesium, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

PreviDent (sodium fluoride): Calcium, Vitamin D
Prevpac (lansoprazole + amoxicillin + clarithromycin): Licorice, Probiotic Flora, Vitamin C, Vitamin K, Zinc
Prezista (darunavir): Copper, Garlic, St. John's Wort, Vitamin C
Priadel (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan
Prilosec (omeprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Vitamin E, Zinc
Primatene Dual Action (ephedrine + guaifenesin + theophylline): Cayenne, Magnesium
Primatene Mist (epinephrine): Magnesium, Potassium, Vitamin C
Primaxin I.M. (imipenem + cilastatin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Primaxin I.V. (imipenem + cilastatin): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B1, Vitamin K, Zinc
Primobolan (methenolone enanthate): Echinacea
Principen (ampicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin C, Vitamin K, Zinc
Prinivil (lisinopril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc
Prinzide (lisinopril + hydrochlorothiazide): Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc
Pro-Banthine (propantheline bromide): Vitamin B_2
Probalan (probenecid): Vitamin B_2, Vitamin B_3, Vitamin C
Procan-SR (procainamide): Cascara, Magnesium, Potassium
Procardia (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Procrit (epoetin alpha): Dang Gui, Iron, Vitamin B_6, Vitamin C
Proctocort (hydrocortisone): Aloe, Green Tea, Licorice, Vitamin C
Procur (cyproterone): Black Cohosh, Vitamin D
Procytox (cyclophosphamide): Aloe, Alpha-Lipoic Acid, Astragalus, Beta-Carotene, Carnitine, Echinacea, Eleuthero, Ginger, Ginseng, Licorice, Melatonin, Omega-3 Fatty Acids, Reishi, Selenium, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E
Progout (allopurinol): Carnitine, Copper, Iron, Tryptophan, Vitamin D
Prograf (tacrolimus): Echinacea, St. John's Wort
Progyluton (estradiol valerate + norgestrel): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Progynova (estradiol valerate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc
Prokine (GMCSF): Echinacea
Proleukin (aldesleukin): Astragalus, Echinacea, Melatonin
Prolixin (fluphenazine): Chromium, Coenzyme Q10, Ginkgo, Kava, Melatonin, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Prolixin Decanoate (fluphenazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Prolixin Enanthate (fluphenazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Proloprim (trimethoprim): Folic Acid, Licorice, Probiotic Flora, Vitamin B_2, Vitamin K, Zinc
Promacot (promethazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Promethegan (promethazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C
Prometrium (progesterone, micronized): Vitamin D
Pronap-100 (acetaminophen + propoxyphene): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Pronestyl (procainamide): Cascara, Magnesium, Potassium
Pronil (secnidazole): Milk Thistle
Propacet 100 (acetaminophen + propoxyphene): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Propagest (phenylpropanolamine): Potassium, Tyrosine
Propecia (finasteride): Black Cohosh, Saw Palmetto
Propoxacet-N (acetaminophen + propoxyphene): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Proscar (finasteride): Black Cohosh, Saw Palmetto
ProSom (estazolam): DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3
Protium (pantoprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc
Protonix (pantoprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc
Protostat (metronidazole, systemic): Licorice, Milk Thistle, Probiotic Flora, Vitamin K, Zinc
Provel (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Proventil (albuterol): Calcium, Magnesium, Potassium
Provera (medroxyprogesterone, oral): Beta-Carotene, Calcium, Folic Acid, Magnesium, St. John's Wort, Vitamin A, Vitamin D
Provigil (modafinil): Reishi, Tyrosine
Prozac (fluoxetine): 5-HTP, Chromium, DHEA, Folic Acid, Ginkgo, Inositol, Melatonin, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc
Psorcon (diflorasone): Aloe, Green Tea, Licorice, Vitamin C
Pulmadil (rimiterol): Calcium, Magnesium, Potassium
Pulvules (cinoxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Pump-Hep (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D
Purinethol (mercaptopurine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_3
Questran (cholestyramine): Beta-Carotene, Calcium, Folic Acid, Iron, Magnesium, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc
Quick Pep (caffeine): Calcium, Ephedra, Kava, Melatonin
Quilonum SR (lithium carbonate): 5-HTP, Chromium, Folic Acid, Inositol, Magnesium, Tryptophan
Quinaglute (quinidine): Beta-Carotene, Cascara, Magnesium, Potassium
Quinidex (quinidine): Beta-Carotene, Cascara, Magnesium, Potassium
Quinora (quinidine): Beta-Carotene, Cascara, Magnesium, Potassium

QVAR (beclomethasone inhalant): Calcium
Rebetol (ribavirin): *S*-Adenosylmethionine (SAMe)
Rebetron (ribavirin + interferon alpha-2b): Iron, Licorice, Zinc
Rederm (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Reductil (sibutramine): 5-HTP, Tryptophan
Refludan (lepirudin): Cayenne, DHEA, Policosanol
Reglan (metoclopramide): Vitamin B_3, Zinc
Regular Strength Bayer Enteric 500 Aspirin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc
Regulin (betanidine): Ephedra
Relafen (nabumetone): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Relaxazone (chlorzoxazone): Garlic, St. John's Wort
Relpax (eletriptan): 5-HTP, Feverfew, Tryptophan
Remeron (mirtazapine): Melatonin
Remicade (infliximab): Echinacea
Remular-S (chlorzoxazone): Garlic, St. John's Wort
Rendix (dabigatran): Cayenne, DHEA, Policosanol
Renese (polythiazide): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc
Renova (tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E
ReoPro (abciximab): Cayenne, Ginger, Policosanol, *S*-Adenosylmethionine (SAMe)
Reprexain (hydrocodone + ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Ginseng, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Reprexain (ibuprofen + hydrocodone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Rescriptor (delavirdine): St. John's Wort, Vitamin B_2
Restoril (temazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3
Retavase (reteplase, recombinant): Astragalus
Retin-A (tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E
Retrovir (zidovudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc
Revasc (desirudin): Cayenne, DHEA, Policosanol
Reyataz (atazanavir): Copper, Garlic, St. John's Wort, Vitamin C
Rheumatrex (methotrexate): Aloe, Beta-Carotene, Echinacea, Eleuthero, Folic Acid, Garlic, Ginseng, Iron, Melatonin, Milk Thistle, Omega-3 Fatty Acids, PABA, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E
Rhindecon (phenylpropanolamine): Potassium, Tyrosine
Ribasphere (ribavirin): *S*-Adenosylmethionine (SAMe)
Ridafed (pseudoephedrine): Potassium
Rifadin (rifampicin): Folic Acid, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E
Rifadin IV (rifampicin): Folic Acid, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E
Rifamate (isoniazid + rifampicin): Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E
Rifater (isoniazid + pyrazinamide + rifampicin): Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E
Rimactane (isoniazid + rifampicin): Calcium, Copper, Folic Acid, Magnesium, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D, Vitamin E
Risperdal (risperidone): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B6, Vitamin C, Vitamin E
Ritalin (methylphenidate): 5-HTP, Iron, Reishi, Tyrosine, Zinc
Ritalin-SR (methylphenidate): 5-HTP, Iron, Reishi, Tyrosine, Zinc
Rivotril (clonazepam): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
RMS (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Robicillin VK (penicillin V): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Rocephin (ceftriaxone): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc
Roferon-A (interferon alpha): Astragalus, Echinacea, Iron, Licorice, Zinc
Rowasa (mesalazine): Vitamin B_{12}
Roxanol (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Roxanol Rescudose (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Roxanol T (morphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Roxicet 5/500 (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Roxicodone (oxycodone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine
Roxilox (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C
Rubex (doxorubicin): Aloe, Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Ginseng, Green Tea, Hawthorn, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin B_2, Vitamin C, Vitamin D, Vitamin E
Rufen (ibuprofen): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
S-2 (epinephrine): Magnesium, Potassium, Vitamin C
S-T Cort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Sabril (vigabatrin): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Salazopyrin (sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Salazopyrin EN-Tabs (sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Salflex (salsalate): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Policosanol, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin K, Zinc

Salofalk (mesalazine): Vitamin B_{12}

Salsitab (salsalate): Calcium, Folic Acid, Omega-3 Fatty Acids, Policosanol, Vitamin C, Vitamin K, Zinc

Sandimmune (cyclosporine): Arginine, Echinacea, Ginkgo, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, St. John's Wort, Turmeric/Curcumin, Vitamin C, Vitamin E, Zinc

SangCya (cyclosporine): Arginine, Echinacea, Ginkgo, Magnesium, Melatonin, Omega-3 Fatty Acids, Potassium, St. John's Wort, Turmeric/Curcumin, Vitamin C, Vitamin E, Zinc

Sarafem (fluoxetine): 5-HTP, Chromium, DHEA, Folic Acid, Ginkgo, Inositol, Melatonin, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

SAS (sulfasalazine): Calcium, Folic Acid, Iron, Licorice, Magnesium, Omega-3 Fatty Acids, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Scopace Tablet (scopolamine): Dang Gui, Vitamin B_1

Seclopen (benzyl + procaine penicillin): Vitamin C

Seconal (secobarbital): DHEA, Gotu Kola, Valerian, Vitamin B_2

Sectral (acebutolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Selexid (pivmecillinam): Carnitine

Selpak (selegiline): 5-HTP, Cayenne, Chromium, Eleuthero, Ephedra, Folic Acid, Ginkgo, Iron, Kava, Licorice, Phenylalanine, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_2, Vitamin B_6, Vitex

Senexon (senna): Potassium

Senna-Gen (senna): Potassium

Senokot (senna): Potassium

Senolax (senna): Potassium

Septra (trimethoprim + sulfamethoxazole): Calcium, Folic Acid, Licorice, Magnesium, PABA, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin C, Vitamin K, Zinc

Serax (oxazepam): DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Serentil (mesoridazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Serevent (salmeterol): Calcium, Magnesium, Potassium

Seromycin (cycloserine): Calcium, Folic Acid, Magnesium, Milk Thistle, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D

Seroquel (quetiapine): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C

Seroxat (paroxetine): 5-HTP, Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Serzone (nefazodone): St. John's Wort

Sevorane (sevoflurane): Aloe, Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Silvadene (silver sulfadiazine): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Sinemet (levodopa + carbidopa): 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Sinemet CR (levodopa + carbidopa): 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Vitex

Sinequan (doxepin): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Sintrom (nicoumalone): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Siterone (cyproterone): Black Cohosh, Vitamin D

Skelid (tiludronate): Calcium, Iron, Magnesium, Vitamin D, Zinc

Sleep Aid (doxylamine): Vitamin B_6

Slo-Bid (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6

Slo-Phyllin (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6

Slofedipine XL (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Snap Back (caffeine): Calcium, Ephedra, Kava, Melatonin

Sodium Sulamyd (sodium sulfacetamide): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Solfoton (phenobarbital): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Reishi, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Soma Compound (ASA + carisoprodol): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk, Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2 Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Somac (pantoprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, St. John's Wort, Vitamin B_{12}, Zinc

Sonata (zaleplon): Gotu Kola, Melatonin, Valerian

Sorbitrate (isosorbide dinitrate): Arginine, Carnitine, Folic Acid, Vitamin C

Soriatane (acitretin): Beta-Carotene, Calcium, Carnitine, Omega-3 Fatty Acids, Vitamin A, Vitamin E

Sorine (sotalol): Calcium, Carnitine, Cascara, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Spectazole (econazole): Echinacea

Spectracef (cefditoren pivoxil): Carnitine

Spectrobid (bacampicillin): Ginseng, Green Tea

Sporanox (itraconazole): Echinacea, St. John's Wort

SSD (silver sulfadiazine): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

St Joseph Adult Chewable Aspirin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Stadol (butorphanol): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Stadol NS (butorphanol): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Stagesic (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Stalevo (levodopa + carbidopa + entacapone): 5-HTP, Folic Acid, Iron, Kava, Methionine, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin B_6, Vitamin C, Vitex

Starlix (nateglinide): Chromium, Vitamin B_3

Stay Alert (caffeine): Calcium, Ephedra, Kava, Melatonin

Stelazine (trifluoperazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Stemetil (prochlorperazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Stilnoct (zolpidem): 5-HTP, Gotu Kola, Melatonin, Valerian

Stilphostrol (diethylstilbestrol): Black Cohosh

Streptase (streptokinase): Astragalus

Sublimaze Injection (fentanyl): Ephedra, Ginger, Ginseng, Gotu Kola, Magnesium, Phenylalanine, Tyrosine

Suboxone (buprenorphine + naloxone): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Subutex (buprenorphine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Sudafed (pseudoephedrine): Potassium

Sudrine (pseudoephedrine): Potassium

Sular (nisoldipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Sulfatrim Pediatric (trimethoprim + sulfamethoxazole): Calcium, Folic Acid, Licorice, Magnesium, PABA, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_2, Vitamin B_6, Vitamin C, Vitamin K, Zinc

Sultrin Triple Sulfa (triple sulfa): Calcium, Folic Acid, Licorice, Magnesium, PABA, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Sumycin (tetracycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Superlipid (probucol): Beta-Carotene

Suphedrin (pseudoephedrine): Potassium

Suprane (desflurane): Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Suprax (cefixime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Surfak (docusate): Magnesium, Potassium

Surmontil (trimipramine): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, Potassium, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Sus-Phrine (epinephrine): Magnesium, Potassium, Vitamin C

Suspen (penicillin V potassium): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Sustiva (efavirenz): St. John's Wort, Vitamin B_2

Symbyax (olanzapine): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Synacort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Synelar (fluocinolone): Aloe, Green Tea, Licorice, Vitamin C

Synemol (fluocinolone): Aloe, Green Tea, Licorice, Vitamin C

Synthroid (levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Syntocinon (oxytocin): Ephedra

Syprine (trientine): Copper, Iron

T-Gesic (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Tabloid (thioguanine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1, Vitamin B_2

Tace (chlorotrianisene): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Tagamet (cimetidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Vitamin D, Zinc

Tagamet HB (cimetidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Vitamin D, Zinc

Talacen (acetaminophen + pentazocine): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Methionine, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Talwin (pentazocine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Talwin Compound (acetylsalicylic acid + pentazocine): Calcium, Ephedra, Folic Acid, Ginseng, Gotu Kola, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, Phenylalanine, Potassium, Tyrosine, Vitamin B_2, Vitamin B_3, Vitamin E

Talwin NX (pentazocine): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Tambocor (flecainide): Cascara, Magnesium, Potassium

Tao (troleandomycin): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Tarabine PFS (cytarabine): Echinacea, Eleuthero, Folic Acid, Ginseng, Vitamin B_1

Targretin (bexarotene): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Tarka (trandolapril + verapamil): Arginine, Calcium, Coenzyme Q10, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin E

Taxol (paclitaxel): Aloe, Beta-Carotene, Echinacea, Eleuthero, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, PABA, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin C, Vitamin E

Taxotere (docetaxel): Aloe, Beta-Carotene, Echinacea, Eleuthero, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort, Turmeric/Curcumin, Vitamin A, Vitamin B_6, Vitamin C, Vitamin E

Tazicef (ceftazidime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Tazidime (ceftazidime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Tebrazid (pyrazinamide): Folic Acid, Milk Thistle, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin D

Tegison (etretinate): Beta-Carotene, Calcium, Carnitine, Omega-3 Fatty Acids, Vitamin A, Vitamin E

Tegretol (carbamazepine): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Teladar (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Temodar (temozolomide): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Temovate (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc
Tempo Tablets (aluminum hydroxide + magnesium hydroxide + calcium carbonate + simethicone): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Magnesium, Vitamin A, Vitamin B_1, Vitamin C, Vitamin D, Vitex, Zinc
Tenif (atenolol + nifedipine): Arginine, Calcium, Coenzyme Q10, Dang Gui, Magnesium, Policosanol, Potassium, St. John's Wort, Vitamin C
Tenoretic (atenolol + chlorthalidone): Arginine, Calcium, Coenzyme Q10, Policosanol, Potassium, Vitamin C
Tenormin (atenolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C
Tensipine MR (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto
Teolit (testolactone): Beta-Carotene, DHEA, Vitamin A, Zinc
Tequin (gatifloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Terramycin (oxytetracycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Teslac (testolactone): Beta-Carotene, DHEA, Vitamin A, Zinc
Teslak (testolactone): Beta-Carotene, DHEA, Vitamin A, Zinc
Testred (methyltestosterone): Beta-Carotene, DHEA, Vitamin A, Zinc
Tetracyn (tetracycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc
Tetrathiomolybdate (tetrathiomolybdate): Copper, Zinc
Teveten (eprosartan): Alpha-Lipoic Acid, Potassium
Texacort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C
Theo-24 (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6
Theo-Bid (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6
Theo-Dur (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6
Theocron (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6
Theolair (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6
Thiopental (thiopentone): DHEA, Ginger, Gotu Kola, Valerian, Vitamin B_2
Thioplex (thiotepa): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium
Thioprine (azathioprine): Echinacea, Folic Acid, Vitamin B_3
Thorazine (chlorpromazine): Chromium, Coenzyme Q10, Ginkgo, Kava, Melatonin, Milk Thistle, Reishi, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Vitamin E
Thyar (L-thyroxine + L-triiodothyronine, synthetic): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
Thyrolar (L-thyroxine + L-triiodothyronine, synthetic): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2
Tiamate (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Tiazac (diltiazem): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D
Tiberal (ornidazole): Milk Thistle
Ticar (ticarcillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Ticlid (ticlopidine): Bilberry, Cayenne, Feverfew, Garlic, Ginger, Ginkgo, Omega-3 Fatty Acids, Policosanol, *S*-Adenosylmethionine (SAMe)
Tikosyn (dofetilide): Cascara, Magnesium, Potassium
Timentin (ticarcillin + clavulanic acid): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc
Tindamax (tinidazole): Milk Thistle
Titralac (calcium carbonate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin D, Zinc
TOBI (tobramycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
TOBI Solution (tobramycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Tobradex (dexamethasone + tobramycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Tobrex (tobramycin): Alpha-Lipoic Acid, Calcium, Eleuthero, Ginger, Ginkgo, Horse Chestnut, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin B_{12}, Vitamin K
Tofranil (imipramine): 5-HTP, Coenzyme Q10, Echinacea, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc
Tol-Tab (tolbutamide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B_3
Tolectin (tolmetin): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_5, Vitamin B_6, Vitamin C, Zinc
Tolinase (tolazamide): Aloe, Alpha-Lipoic Acid, Astragalus, Bilberry, Chromium, Coenzyme Q10, DHEA, Ephedra, Garlic, Ginkgo, Ginseng, Glucosamine Sulfate, Gotu Kola, Horse Chestnut, Magnesium, Omega-3 Fatty Acids, Reishi, Turmeric/Curcumin, Vitamin B3
Tomudex (raltitrexed): Echinacea, Eleuthero, Folic Acid, Vitamin B_1
Topamax (topiramate): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Potassium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc
Topicort (desoximetasone): Aloe, Green Tea, Licorice, Vitamin C
Topicort LP (desoximetasone): Aloe, Green Tea, Licorice, Vitamin C
Topifort (clobetasol): Aloe, Green Tea, Licorice, Vitamin C, Zinc

Toradol (ketorolac): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Torecan (thiethylperazine): Milk Thistle

Totacillin (ampicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin C, Vitamin K, Zinc

Tracrium (atracurium): Ginger, Magnesium

Tramake (tramadol): 5-HTP

Trandate (labetalol): Potassium

Transderm Scop Patch (scopolamine): Dang Gui, Vitamin B_1

Transderm-Nitro (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Tranxene (clorazepate): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Gotu Kola, Inositol, Kava, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Tryptophan, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Trasicor (oxprenolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Trasidrex (oxprenolol + cyclopenthiazide): Arginine, Calcium, Coenzyme Q10, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Trecator SC (ethionamide): Folic Acid, Milk Thistle, Vitamin B_6, Vitamin C, Vitamin D

Trelstar LA (triptorelin): Black Cohosh, Melatonin, Vitamin D

Trental (pentoxifylline): Arginine, Cayenne, Coenzyme Q10, Policosanol, Vitamin E

Tri-Levlen (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Tri-Norinyl (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Triaminic A.M. (pseudoephedrine): Potassium

Triapin (felodipine + ramipril): Arginine, Calcium, Coenzyme Q10, Magnesium, Potassium, St. John's Wort

Triavil (amitriptyline + perphenazine): Coenzyme Q10, Echinacea, Milk Thistle, St. John's Wort, Vitamin B_{12}

Tricor (fenofibrate): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Zinc

Tridesilon (desonide): Aloe, Green Tea, Licorice, Vitamin C

Tridil (nitroglycerin): Arginine, Carnitine, Folic Acid, Vitamin C

Tridione (trimethadione): Carnitine, Folic Acid

Trifluperidol (triperidol): Milk Thistle, Phenylalanine

Triglide (fenofibrate): Coenzyme Q10, Copper, Folic Acid, Gotu Kola, Omega-3 Fatty Acids, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Zinc

Trilafon (perphenazine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Trileptal (oxcarbazepine): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Trimovate (neomycin + nystatin + clobetasone): Aloe, Beta-Carotene, Green Tea, Licorice, Vitamin C, Zinc

Trimox (amoxicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Trimpex (trimethoprim): Folic Acid, Licorice, Probiotic Flora, Vitamin B_2, Vitamin K, Zinc

Trinovum (ethinyl estradiol + norethindrone): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Triostat (injection) (L-triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Triphasil (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Triptazine (amitriptyline + perphenazine): Coenzyme Q10, Echinacea, Milk Thistle, St. John's Wort, Vitamin B_{12}

Trisequens (estradiol + norethindrone, oral): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Tritec (ranitidine + bismuth + citrate): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc

Trivora (ethinyl estradiol + levonorgestrel): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Trizivir (abacavir + lamivudine + zidovudine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Folic Acid, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Vitamin E, Zinc

Tromexan (ethyl biscoumacetate): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Trovan (trovafloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Truphylline (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6

Trusopt (dorzolamide): Potassium

Truxcillin (penicillin V potassium): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Truxcillin VK (penicillin V): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Tums (calcium carbonate): Calcium, Cayenne, Chromium, Copper, Folic Acid, Iron, Vitamin A, Vitamin B_1, Vitamin D, Zinc

Tylenol (acetaminophen): Dang Gui, Devil's Claw, Garlic, Gotu Kola, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C

Tylenol Cold (acetaminophen + chlorpheniramine + dextromethorphan + pseudoephedrine): Garlic, Licorice, Methionine, Milk Thistle, *S*-Adenosylmethionine (SAMe), Vitamin C

Tylenol with Codeine (acetaminophen + codeine): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Methionine, Milk Thistle, Phenylalanine, *S*-Adenosylmethionine (SAMe), Tyrosine, Vitamin C

Tylox (acetaminophen + oxycodone): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Ultane (sevoflurane): Aloe, Alpha-Lipoic Acid, Ephedra, Milk Thistle, St. John's Wort, Valerian

Ultralan (fluocortolone): Aloe, Green Tea, Licorice, Vitamin C

Ultram (tramadol): 5-HTP

Ultravate (halobetasol): Aloe, Green Tea, Licorice, Vitamin C

Uni-Dur (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6

Unihep (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Uniparin Calcium (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Uniparin Forte (heparin): Calcium, Cayenne, Chondroitin Sulfate, DHEA, Omega-3 Fatty Acids, Policosanol, Potassium, Vitamin C, Vitamin D

Unipen (nafcillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Uniphyl (theophylline): Arginine, Cayenne, Ephedra, Magnesium, Melatonin, Potassium, St. John's Wort, Vitamin B_6

Unipine XL (nifedipine): Black Cohosh, Calcium, Dang Gui, Magnesium, Saw Palmetto

Unisom (doxylamine): Vitamin B_6

Unisyn (ampicillin + sulbactam): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Unithroid (levothyroxine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Unitrol (phenylpropanolamine): Potassium, Tyrosine

Univasc (moexipril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Urdox (ursodeoxycholic acid): *S*-Adenosylmethionine (SAMe), Vitamin B_3

Urso (ursodeoxycholic acid): *S*-Adenosylmethionine (SAMe), Vitamin B_3

Ursofalk (ursodeoxycholic acid): *S*-Adenosylmethionine (SAMe), Vitamin B_3

Ursogal (ursodeoxycholic acid): *S*-Adenosylmethionine (SAMe), Vitamin B_3

Uticort (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Utrogestan (progesterone, micronized): Vitamin D

V-Cillin K (penicillin V): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Vagifem (estradiol hemihydrate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Valergen 20 (estradiol valerate): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Valisone (betamethasone dipropionate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Valium (diazepam): Carnitine, DHEA, Gotu Kola, Melatonin, Valerian, Vitamin B_3

Vancenase (beclomethasone inhalant): Calcium

Vancenase AQ (beclomethasone inhalant): Calcium

Vanceril (beclomethasone inhalant): Calcium

Vancocin (vancomycin): Licorice, Probiotic Flora, Vitamin K, Zinc

Vanos (fluocinonide): Aloe, Green Tea, Licorice, Vitamin C

Vanticon (zafirlukast): Melatonin

Vantin (cefpodoxime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Vascor (bepridil): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Vaseretic (enalapril + hydrochlorothiazide): Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Vasotec (enalapril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Vasoxyl (methoxamine): Melatonin

Vectrin (minocycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Veetids (penicillin V potassium): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Velban (vinblastine): Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin

Velocef (cephradine): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Velsar (vinblastine): Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin

Ventolin (albuterol): Calcium, Magnesium, Potassium

Vepesid (etoposide): Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort

Vercyte (pipobroman): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Verelan (verapamil): Calcium, Carnitine, Folic Acid, Magnesium, Melatonin, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E

Verelan PM (verapamil): Calcium, Carnitine, Folic Acid, Magnesium, Melatonin, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E

Versed (midazolam): DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3

Vesanoid (tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Vesprin (trifluprom azine): Coenzyme Q10, Milk Thistle, Vitamin B_2, Vitamin B_3, Vitamin C

Vfend (voriconazole): Echinacea, St. John's Wort

Viagra (sildenafil): Arginine

Vibra-Tabs (doxycycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Vibramycin (doxycycline): Calcium, Folic Acid, Iron, Magnesium, Potassium, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Vicodin (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Vicodin ES (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Vicodin HP (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Vicoprofen (ibuprofen + hydrocodone): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw,

Ephedra, Feverfew, Folic Acid, Ginger, Ginseng, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Phenylalanine, Potassium, Turmeric/Curcumin, Tyrosine, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

Videx (didanosine): Aloe, Carnitine, Coenzyme Q10, Copper, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Vigilon (polyethylene oxide sheet dressing): Aloe

Vika (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Vikela (levonorgestrel, oral postcoital contraceptive): Magnesium, St. John's Wort

Vilona (ribavirin): *S*-Adenosylmethionine (SAMe)

Vincasar PFS (vincristine): Alpha-Lipoic Acid, Echinacea, Eleuthero, Feverfew, Ginseng, St. John's Wort, Turmeric/Curcumin

Vioxx (rofecoxib): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin C, Zinc

Vira-A (vidarabine): Methionine, Reishi, *S*-Adenosylmethionine (SAMe)

Viracept (nelfinavir): Copper, Garlic, St. John's Wort, Vitamin C

Viramune (nevirapine): St. John's Wort, Vitamin B_2

Virazole (ribavirin): *S*-Adenosylmethionine (SAMe)

Viread (tenofovir): Aloe, Carnitine, Coenzyme Q10, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Virilon (methyltestosterone): Beta-Carotene, DHEA, Vitamin A, Zinc

Visken (pindolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Vitinoin (tretinoin): Beta-Carotene, Calcium, Carnitine, Vitamin A, Vitamin E

Vivactil (protriptyline): 5-HTP, Coenzyme Q10, Milk Thistle, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Tyrosine, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Zinc

Vivarin (caffeine): Calcium, Ephedra, Kava, Melatonin

Vivelle-Dot (estradiol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Vivelle Transdermal (estradiol): Arginine, Black Cohosh, Boron, Calcium, Copper, DHEA, Dang Gui, Magnesium, Melatonin, Milk Thistle, St. John's Wort, Vitamin B_6, Vitamin D, Vitamin E, Vitex, Zinc

Voltaren (diclofenac): Calcium, Cayenne, Chondroitin Sulfate, Chromium, Copper, Devil's Claw, Feverfew, Folic Acid, Ginger, Glucosamine Sulfate, Gotu Kola, Iron, Licorice, Melatonin, Omega-3 Fatty Acids, Potassium, Turmeric/Curcumin, Vitamin B_3, Vitamin B_6, Vitamin C, Zinc

VP-16 (etoposide): Aloe, Feverfew, Ginseng, Melatonin, Omega-3 Fatty Acids, St. John's Wort

Vumon (teniposide): St. John's Wort

Warfilone (warfarin): Bilberry, Cayenne, Chondroitin Sulfate, Coenzyme Q10, DHEA, Dang Gui, Devil's Claw, Echinacea, Feverfew, Garlic, Ginger, Ginkgo, Ginseng, Green Tea, Horse Chestnut, Iron, Kava, Licorice, Magnesium, Omega-3 Fatty Acids, Policosanol, Red Clover, Reishi, Saw Palmetto, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Zinc

WelChol (colesevelam): Beta-Carotene, Calcium, Folic Acid, Iron, Omega-3 Fatty Acids, Vitamin A, Vitamin B_2, Vitamin B_3, Vitamin B_{12}, Vitamin D, Vitamin E, Vitamin K, Zinc

Wellbutrin (bupropion): Melatonin

Westcort (hydrocortisone 17-butyrate/acetate/probutate/valerate): Aloe, Green Tea, Licorice, Vitamin C

Westhroid (L-thyroxine + L-triiodothyronine): Alpha-Lipoic Acid, Calcium, Carnitine, Coenzyme Q10, DHEA, Iron, Tyrosine, Vitamin B_2

Winstrol (stanozolol): Echinacea, Iron

Wygesic (acetaminophen + propoxyphene): Ephedra, Garlic, Ginseng, Gotu Kola, Licorice, Milk Thistle, Phenylalanine, Tyrosine, Vitamin C

Wymox (amoxicillin): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Xanax (alprazolam): DHEA, Gotu Kola, Kava, Melatonin, St. John's Wort, Valerian, Vitamin B_3

Xeloda (capecitabine): Echinacea, Eleuthero, Folic Acid, Vitamin B_1

Xenical (orlistat): Beta-Carotene, Coenzyme Q10, Vitamin A, Vitamin D, Vitamin E, Vitamin K

Xopenex (levalbuterol): Calcium, Magnesium, Potassium

Zagam (sparfloxacin): Calcium, Green Tea, Iron, Licorice, Magnesium, Potassium, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Zamadol (tramadol): 5-HTP

Zanidip (lercanidipine): Calcium, Carnitine, Folic Acid, Magnesium, St. John's Wort, Vitamin B_6, Vitamin D

Zanosar (streptozocin): Astragalus, Carnitine, Echinacea, Eleuthero, Selenium

Zantac (ranitidine): Calcium, Chromium, Copper, Folic Acid, Iron, Licorice, Magnesium, Vitamin B_{12}, Vitamin C, Zinc

Zarontin (ethosuximide): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

Zaroxolyn (metolazone): Calcium, Coenzyme Q10, Folic Acid, Ginkgo, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin B_2, Vitamin D, Zinc

Zavedos (idarubicin): Alpha-Lipoic Acid, Carnitine, Coenzyme Q10, Feverfew, Garlic, Ginkgo, Green Tea, Hawthorn, Milk Thistle, Reishi, Selenium, St. John's Wort, Turmeric/Curcumin, Vitamin B_2, Vitamin E

Zebeta (bisoprolol): Calcium, Carnitine, Chromium, Coenzyme Q10, Folic Acid, Magnesium, Melatonin, Potassium, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin C

Zentel (albendazole): Beta-Carotene, Vitamin A

Zerit (stavudine): Aloe, Carnitine, Coenzyme Q10, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Zestoretic (lisinopril + hydrochlorothiazide): Arginine, Calcium, Cayenne, Coenzyme Q10, Glucosamine Sulfate, Hawthorn, Licorice, Magnesium, Potassium, Vitamin D, Zinc

Zestril (lisinopril): Arginine, Cayenne, Iron, Omega-3 Fatty Acids, Potassium, Vitamin E, Zinc

Zetia (ezetimibe): Policosanol

Ziagen (abacavir): Aloe, Carnitine, Coenzyme Q10, DHEA, Reishi, Vitamin B_1, Vitamin B_2, Vitamin B_{12}, Zinc

Zinacef (cefuroxime): Ginseng, Green Tea, Iron, Licorice, Probiotic Flora, Reishi, Vitamin B_1, Vitamin K, Zinc

Zithromax (azithromycin): Calcium, Green Tea, Magnesium, Probiotic Flora, Vitamin B_1, Vitamin B_6, Vitamin K, Zinc

Zocor (simvastatin): Beta-Carotene, Carnitine, Coenzyme Q10, Garlic, Gotu Kola, Omega-3 Fatty Acids, Policosanol, Reishi, Selenium, St. John's Wort, Vitamin A, Vitamin B_3, Vitamin B_{12}, Vitamin C, Vitamin E

Zoladex (goserelin): Black Cohosh, Vitamin D

Zoloft (sertraline): Chromium, Folic Acid, Ginkgo, Inositol, Omega-3 Fatty Acids, *S*-Adenosylmethionine (SAMe), St. John's Wort, Tryptophan, Vitamin B_5, Vitamin B_6, Vitamin B_{12}, Vitamin C, Zinc

Zometa (zoledronic acid): Calcium, Iron, Magnesium, Vitamin D, Zinc

Zomig (zolmitriptan): 5-HTP, Feverfew, Tryptophan

Zonegran (zonisamide): Calcium, Carnitine, Copper, DHEA, Folic Acid, Ginkgo, Inositol, Kava, Milk Thistle, Omega-3 Fatty Acids, Potassium, Valerian, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_3, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin D, Vitamin E, Vitamin K, Vitex, Zinc

ZORprin (acetylsalicylic acid): Bilberry, Calcium, Cayenne, Devil's Claw, Feverfew, Folic Acid, Garlic, Ginger, Ginkgo, Gotu Kola, Iron, Licorice, Melatonin, Milk Thistle, Omega-3 Fatty Acids, Policosanol, Potassium, *S*-Adenosylmethionine (SAMe), Vitamin B_2, Vitamin B_3, Vitamin C, Vitamin E, Vitamin K, Zinc

Zosyn (piperacillin + tazobactam): Ginseng, Green Tea, Licorice, Probiotic Flora, Vitamin B_1, Vitamin K, Zinc

Zoton (lansoprazole): Beta-Carotene, Calcium, Chromium, Iron, Kava, Probiotic Flora, St. John's Wort, Vitamin B_{12}, Zinc

Zovia (ethinyl estradiol + ethynodiol): Arginine, Calcium, Copper, DHEA, Dang Gui, Folic Acid, Iron, Licorice, Magnesium, Melatonin, Milk Thistle, *S*-Adenosylmethionine (SAMe), Selenium, St. John's Wort, Tyrosine, Vitamin A, Vitamin B_1, Vitamin B_2, Vitamin B_5, Vitamin B_6, Vitamin B_{12}, Vitamin C, Vitamin E, Vitex, Zinc

Zovirax (acyclovir): Aloe, Astragalus, Folic Acid, Reishi

Zydol (tramadol): 5-HTP

Zydone (hydrocodone + acetaminophen): Ephedra, Ginseng, Gotu Kola, Phenylalanine, Tyrosine

Zyloprim (allopurinol): Carnitine, Copper, Iron, Tryptophan, Vitamin D

Zyprexa (olanzapine): 5-HTP, Chromium, Echinacea, Ginkgo, Melatonin, Omega-3 Fatty Acids, Vitamin B_5, Vitamin B_6, Vitamin C, Zinc

Zyvox (linezolid): Licorice, Probiotic Flora, Vitamin K, Zinc

  vitamin B_{12} and, 338, 344-345
  vitamin C and, 391
  vitamin D and, 399, 405-407
  vitamin E and, 444
  vitamin K and, 453-454

Anticonvulsants—cont'd
vitex and, 172
zinc and, 619, 645
Antidepressants
chromium and, 499, 506-507
coenzyme Q10 and, 732, 742
DHEA and, 755
folic acid and, 186, 210-211
ginkgo and, 69, 75
5-hydroxytryptophan and, 706, 709, 711-712, 713-714, 715
inositol and, 767
melatonin and, 776
milk thistle and, 127-128
omega-3 fatty acids and, 784, 800
SAMe and, 824, 826-827, 829-830
St. John's wort and, 140, 144, 145-146
tryptophan and, 690, 693-694, 696
tyrosine and, 698, 701, 703
vitamin B_1 and, 253, 259
vitamin B_2 and, 264, 276-277
vitamin B_3 and, 282, 298-299, 302
vitamin B_6 and, 307, 332, 335-336
vitamin B_{12} and, 338, 345-346
vitamin C and, 394
zinc and, 618, 631-632
Antiepileptic drugs (AEDs). *See* Anticonvulsants.
Antifolates, folic acid and, 186, 203-206
Antifungals
echinacea and, 37
St. John's wort and, 140, 157
Antihistamines, St. John's wort and, 140
Antihypertensive medications
arginine and, 653, 656
coenzyme Q10 and, 732, 737-738
omega-3 fatty acids and, 802
policosanol and, 809, 812-813
vitamin C and, 356, 369
Anti-inflammatory analgesics, zinc and, 647
Antikaliuretic-diuretic agent, potassium and, 583, 590
Antimalarial drugs, vitamin B_2 and, 263, 269-270
Antimetabolites
echinacea and, 36
folic acid and, 186, 203-206
vitamin B_1 and, 253, 257-258
Antimicrobials
echinacea and, 37
eleuthero and, 41
inositol and, 767
licorice and, 117-118
probiotics and, 815, 819-821
reishi and, 133, 134
vitamin B_1 and, 253, 256-257
vitamin K and, 447, 449-452
zinc and, 618, 628-631
Antimycobacterials, echinacea and, 37
Antineoplastic chemotherapy, eleuthero and, 39, 40-41
Antioxidant(s)
alpha-lipoic acid as, 718-719
arginine and, 660
beta-carotene as, 175
and chemotherapy/radiotherapy, 179-180, 242-243, 369-372
coenzyme Q10 as, 735
melatonin as, 770
methionine and, 681
and statins, 380-381
vitamin B_3 and, 303-304
vitamin C as, 358-359, 364, 365
vitamin E as, 423, 427-428, 445
zinc and, 650
Antiparkinsonian agents
folic acid and, 187, 212-214
5-hydroxytryptophan and, 706, 710-711
iron and, 522, 536-537
SAMe and, 824, 827-828
tyrosine and, 698, 701-702
vitamin B_3 and, 300-301
vitamin B_6 and, 307, 324-325
vitamin C and, 357, 383-384
Antipellagra factor. *See* Vitamin B_3.
Antiplatelet agents
bilberry and, 10
cayenne and, 24-25
chondroitin sulfate and, 730
feverfew and, 51
garlic and, 53, 56-57
ginger and, 62, 64-65
ginkgo and, 69, 72
green tea and, 91
omega-3 fatty acids and, 805
policosanol and, 809, 811-812
SAMe and, 830
Antiprotozoals, milk thistle and, 123, 129
Antipsychotics
atypical
echinacea and, 37
5-hydroxytryptophan and, 715
omega-3 fatty acids and, 802
vitamin B_3 and, 300
vitamin C and, 391-392
chromium and, 507
ginkgo and, 69, 76
melatonin and, 769, 777-778
phenylalanine and, 682, 685, 687-688
vitamin B_2 and, 263, 272
Antiretroviral agents
aloe gel and, 3-4
carnitine and, 661, 673-675
coenzyme Q10 and, 744
copper and, 511, 520-521
DHEA and, 746, 754
echinacea and, 37
folic acid and, 188, 230-231
Antiretroviral agents—cont'd
garlic and, 53, 59-60
St. John's wort and, 140, 146-147
vitamin B_1 and, 253, 261
vitamin B_2 and, 263, 270-271
vitamin B_{12} and, 339, 353-354
Antiscorbutic vitamin. *See* Vitamin C.
Antitubercular agents
folic acid and, 186-187, 211-212
magnesium and, 580
milk thistle and, 127-128
vitamin B_3 and, 281-282, 296-297
vitamin B_6 and, 307, 322-324
vitamin C and, 393
vitamin D and, 399, 414-415
Antivirals
aloe gel and, 3-4
astragalus and, 5, 6
licorice and, 122
reishi and, 133, 134
Anturane (sulfinpyrazone), vitamin B_3 and, 302-303
APAP. *See* Acetaminophen (APAP, paracetamol, Tylenol).
Appetite suppressants, tyrosine and, 704
Apresoline. *See* Hydralazine (Hy, Apresoline).
Arabinoside (Ara A)
methionine and, 681
SAMe and, 830-831
Arachidonic acid cascade inhibitors (AACIs), vitamin A and, 251
Aralen (chloroquine)
calcium and, 492
magnesium and, 580
ARBs (angiotensin II receptor antagonists)
alpha-lipoic acid and, 718, 722
potassium and, 584, 600-601
Arfonad (trimethaphan camsylate), vitamin B_3 and, 301
Arginase, 653
Arginine, 653-660
adverse effects of, 654-655
chemistry and forms of, 653
in clinical practice, 653-654
contraindications to, 655
deficiency of, 654

Check out the companion CD for even more resources!

Find the information you need to continue your learning...

Access this companion CD for ***Herb, Nutrient, and Drug Interactions: Clinical Implications and Therapeutic Strategies*** to view more than 10,000 references and additional literature citations, organized by monograph in order of appearance in the book.

SL425

Understand herb-drug and nutrient-drug interactions to ensure patient safety and enhance clinical outcomes!

Presenting detailed, evidence-based coverage of the most commonly encountered therapeutic agents in modern clinical practice, **Herb, Nutrient, and Drug Interactions: Clinical Implications and Therapeutic Strategies** is your invaluable guide for safe and effective integration of herbal, nutrient, and drug therapies for your patients or clients. Combining pharmaceuticals with herbs or nutrients may complement or interfere with a drug's therapeutic action or may increase adverse effects. Additionally, drug-induced depletion of nutrients can occur. It is critical that you know how herbal and nutritional substances might affect your treatment plan and your patient's health.

Monitor patient choices and develop individualized treatment strategies with confidence!

- **70 comprehensive monographs** of herb-drug and nutrient-drug interactions cover the most commonly used herbs and nutrients in health-related practice and help you coordinate safe, reliable therapy.
- Each herb and nutrient monograph features **summary tables and concise, practical suggestions** that provide quick and easy reference and complement the **systematic review and in-depth analysis**.
- **References included on the bound-in CD** provide high-quality, evidence-based support.
- **An innovative evaluation system and unique icons** differentiate interactions, evaluate evidence, and assess clinical significance.
- Up-to-date information keeps you current with the latest developments in **pharmacology, nutrition, phytotherapy, biochemistry, genomics, oncology, hematology, naturopathic medicine, Chinese medicine, and other fields.**
- A diverse team of **experienced clinicians** lends valuable, trans-disciplinary insight.

"Thorough, accurate, evidence-based information that all practitioners need if they or their patients use herbs or dietary supplements. Highly recommended."

Wayne Jonas, MD
President and Chief Executive Officer
Samueli Institute
Alexandria, Virginia
Former Head of the Office of Alternative Medicine, National Institutes of Health (1995-1998)

"The text is well referenced, balanced, and objective and the use of icons and summary tables allows the clinician to quickly identify areas of potential risk, as well as potential benefit. This book is a major contribution to the field of integrative medicine and an invaluable resource to practitioner and researcher alike."

From the Foreword by
Tieraona Low Dog, MD
Director of Education, Program in Integrative Medicine
Clinical Assistant Professor, Department of Medicine
University of Arizona College of Medicine
Tucson, Arizona

"The most comprehensive and substantiated resource I have seen on drug/herb/nutrient interactions. I was especially impressed by Dr. Stargrove and his interdisciplinary team's ranking of the quality of the available evidence as well as their careful consideration of beneficial interactions, not just adverse effects. Required for every clinician serious about integrative medicine."

Joseph E. Pizzorno, Jr, ND
President Emeritus and Faculty Member
Bastyr University
Kenmore, Washington

"This book, by acknowledged medical experts, offers evidence-based advice on a variety of interactions between conventional drugs, dietary supplements, and herbal medications. The Dietary Supplements Health Education Act (DSHEA) of 1994—the primary regulatory oversight for dietary supplements and herbs—does not provide any of this information. This book does. It also provides valuable information on a variety of other interactions, such as the fact that patients on the cholesterol-lowering medications known as statins (HMG-CoA reductase inhibitors) have depleted levels of Coenzyme Q10. I wholeheartedly recommend this book for its thoughtful, balanced, and well-referenced presentation integrating scientific evidence with practical clinical experience."

David S. Riley, MD
Editor in Chief, EXPLORE: The Journal of Science and Healing
Clinical Associate Professor
University of New Mexico Medical School
